Three Lectures

ON

THE PRACTICAL POINTS IN THE TREATMENT OF THREATENED ASPHYXIA.

Delivered at the Medical Graduates' College and Polyclinic, Chenies-street, W.C.,

BY ROBERT L. BOWLES, M.D. ST. AND., F.R.C.P. LOND.,

CONSULTING PHYSICIAN TO THE FOLKESTONE HOSPITAL; PHYSICIAN TO ST. ANDREW'S CONVALESCENT HOME.

LECTURE III.[1]

GENTLEMEN,—Having now dealt with the subject of drowning sufficiently, I hope, to make it clear and practical, I will continue with a subject very closely allied to that which we have been considering—namely, stertor and the management of the apoplectic and comatose conditions. Stertor was known to the ancients, and Horace, in one of his Satires, says of a drunken bargee, "*stertitque supinus*," so that it had been recognised, in days long ago, that stertor had some relationship with the supine position of the body. [illegible]tor is the term applied to sounds in the throat, mouth, or the m[illegible] of the air-passages produced by the movements of tongue [illegible]during respiration and occurring in the apoplectic tongue[illegible] conditions. Several varieties may be recognised: (1) cong[illegible], arising from approximation of the alæ nasi towards [illegible] septum by the in-going air, as in the act of sniffing; (2) buccal, due to vibrations of the lips and puffings and flappings of the cheeks *during inspiration or* expiration; (3) palatine, arising from vibrations of the soft palate, whether the breath passes through the mouth or the nose; (4) pharyngeal, caused by the lolling back of the base of the tongue into near contact with the posterior wall of the pharynx; (5) laryngeal: this variety is referrable to vibrations of the chordæ vocales, as in croup and whooping-cough; and (6) mucous: mucous stertor is a term which may be given to the bubbling of air through mucus or fluids in the trachea or larger air-tubes.

All *sounds of an abnormal* character *having their origin* in the larynx, trachea, or bronchi at once give rise in the professional mind to a sense of impending danger. It is felt that the life of the patient is in jeopardy from sudden or more commonly gradual progressive suffocation, ending in death. It is known that some physical changes, intrinsic or extrinsic, have arisen which have narrowed or diminished the lumen of the chief air-ways, and the causes of those physical changes are anxiously and carefully sought for, and, if possible, promptly removed. The subsidence of abnormal sounds implies to the anxious physician the *absence* of at least immediate danger. This danger has not, until quite recently, been so much felt with abnormal sounds having their origin in the nasal, oral, and pharyngeal cavities. In those localities, it is true, they have been observed and noted, and then passed by as of trivial or secondary importance—as having, in fact, no serious bearing on the life or well-being of the patient; but in these portions of the air-ways, as in those lower down, abnormal sound *does* imply danger, not immediate perhaps, or difficult to combat—but that it is a danger, and that it requires all the intelligent care and skill of the physician, will, I think, on reflection, be readily conceded.

Noise, then, in any part of the air-way is a danger signal; its importance the physician must determine. The stertor of the apoplectic state may prove equal in danger to the crowing of the croupy child or the stridor arising from the pressure of a thoracic tumour. *Stertor is therefore a symptom with two* meanings: the noise expresses the mechanical interference and the mechanical interference is an accidental concomitant of the unconsciousness. The accident which determines whether "the stroke" be or be not accompanied by stertor is in most cases due to the accident of the patient's happening or not happening to be upon his back; or should he exhibit stertor while upon his side there must be some derangement of the *ordinary relations* of the pharynx, such as the chin being too near the sternum, the existence of a local œdema,

-tubes, pressure from

rrows *the respiratory*

The German physicians Strümpell, Nothnagel, and others, and the modern French physicians, are, like us, in general agreement as to the symptoms and causes of the apoplectic state, and the same may be said of its treatment. Practically, Dr. Strümpell's entire treatment of the apoplectic attack *is* directed to the relief of arterial tension, and this tension is believed to have some relation with the deep, noisy, stertorous breathing; but what that relation is is left to the imagination. It is clear, however, that the means suggested (bleeding) for the relief of the arterial tension is not looked upon as really trustworthy; the writer shows that he has no abiding faith in the means which he advises. They are suggestions only; he evidently is not fully satisfied of their end and object. I hope to be able to satisfy you that the arterial tension has no direct causal relation with the cerebral hæmorrhage; on the contrary, it is shown to be entirely indirect, and a consequence simply of an easily removeable cause, suffocation, indicated by the stertorous breathing, which, when relieved, *so entirely changes* the symptoms that the question of bleeding or other depleting remedies cannot even be entertained. I have never failed, during long experience, to relieve arterial tension in these cases by removing the obstructions which cause the stertor, and by so doing I have at the same time found the nature of the attack to be made more clear and the management of it more simple and effective.

The first effect of a cerebral hæmorrhage is shock, which produces a tendency to syncope; and this state is only *changed by the supervention of stertorous, i.e.,* difficult and suffocative, breathing, when the flushed and turgid countenance, pulsating carotids, and strong bounding pulse at once indicate some powerful reaction. The heart is labouring to overcome some serious obstruction, and it is now obvious enough, from the distension of the systemic capillaries, that such obstruction can only exist in the pulmonary circulation. Nothnagel says, under the head of "Treatment of Apoplexy": "Against the lesion itself nothing is of any avail. The vessel once ruptured the hæmorrhage necessarily follows without our being able to arrest its progress. The treatment, then, ought from the commencement to be exclusively directed against functional troubles, and above all against paralysis of the encephalon. Every effort of the physician should aim at arousing the excitability of the nerve-tissue. Bleeding constitutes—when the general state of the patient permits of it—the most efficacious means It diminishes the intracranial pressure, *arouses circulation in the encephalon*, and combats the hyperæmia which sometimes complicates hæmorrhage and tends to maintain the neurolysis. But if blood-letting is of real service in certain cases, it is in others *strongly* contra-indicated, and it cannot therefore be practised indifferently in all cases of apoplexy without danger." Jaccoud and Hallopeau say: "In the treatment of apoplexy, *it is necessary* above all to be guided by the general condition. When the patient is young, robust, the pulse full and bounding, the cardiac impulse powerful, then *la saignée générale* is *strongly* indicated. Bleeding from the arm is to be preferred. The vein should be opened boldly, so as to obtain a rapid depletion of the circulation. The relief is in certain cases almost immediate, and patients are even seen to regain consciousness during the operation."

The conditions allied to the apoplectic state—i.e., those in which from any cause the mind and will are in abeyance and the body is left in that *state of physical* helplessness in which the functions necessary to the maintenance of life become endangered by forces acting from within and from without—I will briefly touch upon under their respective headings, such as concussion and fracture of the skull, drowning, hæmoptysis, chloroform-poisoning, convulsions, epilepsy, bronchitis, and so on. Each condition I propose to illustrate *by typical cases, in order to demonstrate* to you the varied applications of the principles *contended for.*

Quite early in my investigations I entertained the conviction that by separating the suffocative symptoms from the shock of apoplexy we should so simplify the case as to enable us to mark the position and probable extent of the cerebral mischief. *As I have watched the progressive steps* in the localisation of brain-functions I have become more and more convinced of the practical value of removing the mystifying symptoms of suffocative stertor as an essential element of diagnosis and prognosis, quite independently of the frequent and valuable aid afforded in the final recovery of the stricken and suffering patient. It may be asked whether in any case bleeding is justifiable in apoplexy. A wider knowledge of pathology has taught us that the short-necked, fresh-coloured, plethoric-looking man is not the individual most liable to "a stroke." It is probable that the ordinary appearance of a man in the apoplectic state, with the presence of stertor and suffocative symptoms, and therefore with a congested and turgid countenance, may have led to the error of labeling the plethoric-looking man with the prefix "apoplectic." Of course, such a man may have a stroke, and it is possible that under certain conditions blood-letting may become a question of treatment in the case; but my experience teaches me that even in such constitutions, if no stertor exists and there are no impediments to the free entrance of air into the lungs, the propriety of "letting blood" has never appeared to be necessary or justifiable; the stroke has, through "shock," acted sufficiently as a sedative and removed all traces of bounding pulse and arterial tension. It is conceivable that the circulatory centre may in some cases be fretted by poisoned or disordered blood and that arterial excitability and tension may result from excitability of nerve-tissue, even without obstruction in the air-way; if so, of course blood-letting may be useful and permissible; but in apoplexy I have never seen such a necessity when all respiratory difficulties have been removed.

---

[1] Lectures I. and II. were published in THE LANCET of June 22nd (p. 1748) and 29th (p. 1814), 1901, respectively.

CASE 1.—In November, 1857, I was called to see an old lady who had been attacked with sudden sickness whilst talking to some friends; faintness followed, with an inability to express herself, though she was to a considerable extent conscious. She was put to bed and kept quiet; mustard poultices were applied to the epigastrium and to the nape of the neck and hot bottles to the feet. In an hour or two reaction commenced, and *pari passu* coma and stertorous breathing set in, which steadily increased in intensity until my second visit, when this condition had lasted about three hours. Her pulse was now full and excited, but as she was 73 years of age, and had already suffered from two or three attacks of paralysis, no severe measures were adopted. The skin was hot and covered with a profuse perspiration, the face was swollen and livid, and the mouth was half open, the pupils were contracted and insensible to light, and the eyeball was insensible to touch. The stertor was very deep and the breathing was laboured. Whilst I was at the bedside of my patient she was very nearly suffocated from the stomach ejecting a portion of its contents into the throat. I at once turned her on to her side and emptied her mouth, and she then breathed not only freely but without the slightest stertor. I was somewhat surprised, but proceeded to place her in what appeared to be the most comfortable position—on her back; her respiration instantly ceased and she convulsively struggled for breath. Supposing it to be the tongue which had choked her I thrust my finger into the mouth, and hooked it forward from the base, when the breathing again became easy and free from stertor. The patient was now laid comfortably on her side; and until her death, which took place two days afterwards, the stertor never recurred when she was in that position, but the respiration continued as naturally as if she slept. To convince myself that this was due to position I several times turned her on to her back for a few moments and invariably, when I did so, the *stertor was as marked* as ever. The lateral position had another advantage, for it allowed the saliva and mucus to drain away instead of remaining in the bronchial tubes and giving rise to "mucous stertor," and thus offering another impediment to the respiration. Other changes occurred coincidently with the change of position. The pulse became calmer, the skin cooler and less bedewed with moisture, the eye sensible to touch, and general sensation returned to such an extent that the patient evinced signs of discomfort at the removal of a mustard poultice. Nevertheless, whenever the supine position was adopted, the stertor, difficulty of breathing, lividity of face, and other unfavourable symptoms returned in full force. It was easy to observe that as the position was changed to the back the paralysed tongue gravitated downwards and backwards.

This case suggests many important points for consideration:—1. That the paralysed tongue may, under certain circumstances, cause even death by suffocation; for I believe that this patient would have died if I had not been present when the tongue fell so suddenly back and when the fluid was ejected from the stomach into the throat. 2. That s arises from the tongue falling back in the supine position the body, thus offering a serious impediment to the tion, since it required greater muscular force to breathe stertor than when the respiration was noiseless. 3. That saliva and mucus (other respiratory impediments) drain away when the patient was on her side. 4. That improvement of the general symptoms occurred upon establishment of easy breathing in the lateral position—pu skin, and sensation all undergoing material alterations for better.

CASE 2.—A man, aged 65 years, became comatose exhaustion supervening upon extensive subacute inflammati of emphysematous lungs. When I entered the room he lying on his back with his mouth open, breathing st rously, though not to a great extent. On looking into th mouth the soft palate appeared remarkably small shrivelled, so that it did not come very decidedly into with the tongue, even though partially paralysed. Whilst was standing at the bedside my patient suddenly ceased t breathe, became very livid in the face, struggled convulsiv and then became rigid. My recollection of the first induced *me to turn this patient on to his side*, when h instantly recovered with a long groan and then breathed quite naturally. He was turned on to his back again; returned and he became choked from a quantity of bronch secretion. The lateral position was resumed, the mucus an saliva drained away, and he now breathed quite easily un his death which took place about half an hour afterwards.

CASE 3.—This was a severe epileptic attack with ster which disappeared at once in the lateral position a patient recovered. In this case, too, as in Case 1, and pulse altered in character as the stertor ceased such a case that "position" can be a curative as palliative measure. Here was a delicate man, subj epilepsy and disease of the mitral valves. Supposing breathing to have gone on with great labour and the lungs have become more and more congested, and consequently brain and heart also, one or other or both of these vi organs might have suffered and death ensued.

It is well known that the cavity of the pharynx, having only a fixed boundary posteriorly, may have its capacity materially affected by the ever-varying position of the sides, of the soft palate, the tongue, and the larynx. The and sides of the pharynx have, I believe, but little connexi with the cause of stertor; I shall therefore not further refer to them. The tongue, being attached to the lower jaw by its mucous membrane and its muscles, has its relations with surrounding parts altered as the mouth is opened or closed. When the mouth is closed the horizontal portion or body of the jaw forms nearly a right angle with the spinal column, from which the symphysis is then at its greatest distance. When the mouth is opened by the dropping of the jaw the symphysis describes the arc of a circle and approaches more nearly to the spine, where the posterior wall of the pharynx is attached. The tongue, having its chief attachment to the symphysis, would consequently be drawn away from the pharynx in the former case and allowed to rest in contact with it in the latter. This, if not true in every case, is at least true in some. A dissection was made with great care, so as not to displace the parts more than was necessary to give a fair view of the base of the tongue and the epiglottis. When the mouth was open and the subject on its back the road to the larynx was completely obstructed, in consequence of the tongue resting in contact with the back of the pharynx; but the obstruction could be removed by hooking the tongue upward and forward from its base. When the mouth was closed the tongue was lifted from the pharynx, leaving ample breathing space. But even with the closed mouth, if the chin were much bent on the sternum the base of the tongue was almost in contact with the back of the pharynx. It would seem from this dissection that the muscles of the tongue attaching it to the symphysis of the jaw are ordinarily too short to admit of the base of the tongue reaching the back of the throat when the mouth is closed and the head is thrown back. The purpose served by such an arrangement would appear to be to keep the base of the tongue away from the back of the throat during deglutition. In the act of deglutition the mouth is firmly closed, and the genio-hyoid and genio-hyo-glossi muscles, taking their fixed point from the now immovable symphysis, draw the body of the tongue upwards and forwards, allowing sufficient room for the morsel of food to travel easily through the cavity of the pharynx.

Were these muscles of greater length the base of the tongue might become a source of inconvenience if not of danger. The dissection, besides demonstrating the respective positions of the tongue with the open and the closed mouth, suggests the necessity of caution being used in raising the head with pillows; for if the head be too much bent forward on the chest the tongue may lie in dangerous proximity to the pharynx, even when the mouth is closed.

The different characters of stertor.—From having observed the snoring of sleep sometimes to take place through the nostrils with the closed mouth, and sometimes through the open mouth, and having also observed differences in the apoplectic stertor, I endeavoured to analyse the particular cause of each of these varieties by some experiments on myself and by clinical observation. I placed myself as nearly as possible in the condition of an apoplectic patient by paralysing my tongue, or rather by allowing it to assume its own position by gravitation. After a little practice, and with some care, I succeeded in effecting this. 1. I found that it required much more voluntary effort to snore through the nose and breathe stertorously through the mouth in the upright and prone positions than in the recumbent and supine, and that the greatest impediment to the respiration occurs when the jaw is dropped and the mouth most widely open. 2. I found that the deep, vibrating snore of sleep, with the closed mouth, depends upon the tongue pressing the velum palati upwards and backwards, thus narrowing the opening between the nose and pharynx, the velum vibrating as the air rushes through. Sometimes, when the mouth is partially open, the soft palate drops upon the tongue and vibrates as the air rushes between it and the tongue. To either of these noises in which the soft palate is concerned I have applied the name of "palatine stertor." 3. The harsh, sharp, husky noise occurring in apoplexy, with the mouth wide open, always arises low down in the pharynx, and depends upon the narrowing of the passage between its posterior wall and the base of the tongue. By holding a looking-glass before the face whilst producing this noise, it can readily be seen that the soft palate is in no way concerned in it. In the cases just recorded this was the nature of the stertor which existed, and as it arises solely in the pharynx I have given it the name of "pharyngeal stertor." 4. There is a variety of stertor in apoplexy which may be named "mucous stertor" as it depends upon the presence of mucus in the bronchial tubes. So common is this, either alone or in combination with one or other of the preceding varieties, that in "Hooper's Medical Lexicon" it it stated that "apoplectic stertor appears to depend upon the presence of mucus in the air tubes," as though it were always the cause.

Of these different varieties of stertor, that which is named "pharyngeal" is at first the most dangerous, for the greater the paralysis the more effectually does the tongue block up the passage, and each inspiration only adds to the distress by sucking the tongue lower down into the pharynx. Its danger is, however, not due alone to the gradual impediment it offers to the respiration, but also to the fact that at any moment this impediment may be absolute and cause death by suffocation. This has been before referred to in the remarks upon Case 1. We may observe a similar example in the snoring sleeper who, after drawing several inspirations with evident effort, at last comes to a sudden check from having been gagged by the tongue falling back. This will rouse him from his stupor and he will then sleep on quietly until the same thing recurs from his deepening sleep.

It is admitted that apoplexy may result (and very commonly does result) from an alteration in the state of the general circulation. I conceive that anything which would mischievously affect the circulation during the apoplectic attack would militate very considerably against the chance of the patient's final recovery. Let me suppose a case. A man with disease of the heart or large vessels on making some unusual effort falls down in a fit; he is taken up and laid on his back in bed. Stertor at once begins; if it be not relieved the respiration becomes impeded, venous engorgement of the lungs takes place, then of the right side of the heart, then of the jugulars and of the brain. And now another direct source of apoplexy exists—increased congestion of the brain, and this, too, with unaerated blood, itself a poison sufficient to destroy life. As long, then, as the stertor is allowed to continue the mischief increases and remedies will be of little avail. But suppose that when the man is taken up in a fit of apoplexy he is laid in such a position that his respiration cannot be impeded, that the blood may flow steadily on in its course, that he is placed in such a position, in short, that Nature will meet with no impediment in her attempt to right the temporary disturbance which a sudden effort brought about. Then, I think, we may fairly hope for a better issue, if judicious aid be afforded by means which the urgency of the case may render necessary. This especially applies to cases of congestion dependent upon, or complicated with, atheroma; the danger would then be doubly great, for the increased congestion might be more than the diseased cerebral vessels could bear; they might give way, and the case would become one of sanguineous apoplexy.

In the second class of cases of Dr. John Abercrombie (those not primarily apoplectic), where the symptoms depend upon an effusion of blood in the brain, if there be any hope it must at once be forfeited if the respiration be impeded, since this would increase the congestion of the cerebral vessels and cause the blood to make its way out of those which were ruptured with greater force. The same would apply to laceration of any of the sinuses or vessels of the brain from fracture of the skull. I remember to have seen a boy who had fallen from a bridge brought home in a state of syncope. Extensive simple fracture of the vault of the skull was detected. He was laid on his back on a table, and as reaction commenced he fell into a state of coma with stertorous breathing. In a short time the symptoms became so urgent that trephining was performed, whereupon a large quantity of blood made its escape with considerable force. The boy was relieved, but died three weeks afterwards. On examination after death there was found a large quantity of clotted and fluid blood on the surface of the brain, the superior longitudinal sinus was lacerated, and the substance of the brain was much injured. In a case of this kind, to impede the onward current of blood through the jugulars must be the first step towards death, for the blood would make its way where there was least resistance, through the wound of the sinus. If, however, there were no obstruction in its natural course we may fairly presume that it would follow that, rather than turn aside through an opening in which, perhaps, a coagulum had already formed.

Such, then, are the dangers which may result from a persistence of stertor in apoplectic and similar conditions; but there remain the other and more immediate dangers of the supine position. 1. Fluids or other foreign matters may make their way into the larynx from the mouth or the stomach. This I had repeated opportunities of observing in the dead subject when engaged on our original experiments in 1856; but that it is a real danger in the living man is placed beyond doubt by a remarkable case which is related in the *Medical Times* as having been under the care of the late Dr. Bristowe. A drunken man died from symptoms of suffocation. At the necropsy some of the contents of the stomach were found in the bronchial tubes.

The forms of stertor, then, which have a direct connexion with the apoplectic state are—the palatine, arising from the vibrations of the soft palate; the pharyngeal, from the gravitation of the tongue into the back of the pharynx; and the mucous stertor, from the presence of mucus or other fluids in the larger air-tubes.

CASE 4.—In October, 1863, a woman was seized with apoplexy. On my arrival there was a partial return to consciousness and the left side was found to be paralysed. There was pharyngeal stertor when the patient was in the recumbent posture and she appeared uneasy when she was placed on her right side, so she was placed on her left—the paralysed—side, when the stertor ceased. A blister was applied to the nape of the neck and she remained in this position for nine days. She was now better and spoke to me. Fearing a bedsore I desired the nurse to change her position by turning her from her left on to her right side. Soon after this was done she was distressed for breath and her countenance became livid. On my arrival, a few minutes later, I found the difficulty of breathing gradually increasing, the blistered surface and the ear, upon which she had lain, of a dark purple hue, and the pulse, which had before been weak and irregular, full and bounding. There were large mucous râles over the whole chest; she was quite unconscious, and death from suffocation was imminent. Finding that these symptoms supervened upon the change of position I had her replaced upon her left side, and immediately the pulse sank, the mucous stertor ceased, the breathing was relieved, the lividity of countenance passed away, and the blistered surface, which had been almost black, resumed a bright cherry-red colour. This additional shock, however, proved too much for her, and she died the same day, calm and conscious.

The salient points of this interesting case are: (1) that pharyngeal stertor ceased when the patient was placed on her side; (2) that there was a slow but gradual improvement subsequently to this; (3) that mucous stertor and imminent death supervened when she was placed on the opposite side; (4) that relief was instant on resuming her original position; and (5) that a return to consciousness was coincident with the cessation of stertor—in other words, on the removal of the respiratory difficulty. On a careful examination of the chest after she had become quiet I found all râles slowly fade away from the right side, that which was uppermost, and the natural breathing return; but the left lung, which had been dependent throughout, was dull on percussion and deficient in respiratory murmur. The explanation now became clear—viz., that the dependent lung had become filled with saliva or mucus or froth, and that on changing the side the fluid, by gravitation, was finding its way across the trachea to the opposite lung, but in doing so it had been churned into foam by the ingoing air, giving rise to mucous stertor, and that this foam, by filling up the larger bronchial tubes, was quickly causing suffocation with all its usual results.

As a point of management, then, in a case of apoplexy it would appear necessary to keep the patient on one side and not to change it; but which side should this be? Healthy people when lying on the side breathe chiefly with that side which is uppermost, for the intercostal and other thoracic muscles of the lower side are fixed between the weight of the body and the bed, and the breathing of that side is necessarily almost entirely diaphragmatic.

I have reason to believe that in hemiplegia from progressive disease of the brain a low form of inflammatory action takes place in the lung of the affected side, due to disturbed innervation of the pneumogastric nerve of the same side. In a recent case of tuberculous mass in the centre of the brain which was under my care this was the case and precisely the same distress as above mentioned occurred from mucus when the paralysed side was placed upwards. It must be remembered, too, that in placing the paralysed side downwards the injured side of the brain is upwards, and therefore relieved from congestion, a condition always liable to occur when an injured part remains dependent.

Apoplexy, with much mucous stertor, is, I believe, always of the most grave and dangerous character, for it indicates as well as muscular paralysis loss of function (neuro-paralysis) of such vital nerves as the pneumogastric; and I believe that the time will soon come, now that cases can be so simplified by the removal of stertor, that by a careful consideration of the functions of the various nerves a very accurate diagnosis and prognosis will be arrived at even in the early stage of apoplexy. Here are two cases in illustration.

CASE 5.—A woman was found lying on her back, breathing stertorously and with great difficulty; the trachea was filled with frothy mucus and she was almost in a state of collapse. She was turned on to her right side, when the stertor and difficulty of breathing ceased. Seventeen hours afterwards she was lying quiet and comfortable; the depending cheek was dusky and congested, the upper cheek was pale. She was now turned on to her left side; the difficult breathing immediately returned and both sides of the face became highly congested; the breathing was shallow, and large moist râles were present in both sides of the chest; on resuming the original position all difficulty ceased. She died the next morning.

CASE 6.—A woman was seized on Sept. 24th, 1867, with left hemiplegia. She was unable to speak or to masticate and could only swallow liquids with much difficulty; the pulse was 80 and very feeble. She was placed on her left side. On the 28th (four days after) the respiratory murmur on the lower or left side was shallow and feeble, there were some râles, and the percussion sounds were dull. She was turned on to her right side, when immediately great distress of breathing and mucous stertor supervened; this gradually disappeared on replacing her on her left side. This shows that patients can get well after long resting on their sides. When turned on her back for the use of the bed-pan mucous stertor commenced, and it was noticed that in this position the intercostal muscles and the diaphragm acted more feebly on the paralysed than on the unparalysed side. On Sept. 29th there was a little more power and she was less excitable. The respirations, which had been 56, were now 44. She was able to remain half an hour on the right side before the difficult breathing commenced. The following day she was still better, and the dribbling of saliva, which had been very great, ceased, but she still had no control over her bladder or rectum. On Oct. 6th during the last week she had slowly improved. Several experiments of change of position had been made and it was found that as her power returned she could remain longer on the right side before the difficulty of breathing began, and now could remain one and a half hours in this position. In March, 1870, the patient was still alive and well, but had a good deal of weakness on the left side.

Remarks.—In its early stage this case was most critical. Had a little extra strain been put upon the patient she must have died, and no strain could have been worse than the persistence of a condition (stertorous breathing) which would indirectly cause obstruction in the jugulars. In the supine posture, from the paralysed and insensible condition of the pharynx much of the saliva which dribbled away in the lateral position would have entered the trachea and added to the trouble. Much might be said in illustration of this point and reports of many cases have been sent to me by friends corroborating these observations. They have reported cases of apoplexy in which, on the change of position, stertor has ceased and the patients have died peacefully and quietly, to the great relief of the distressed and sorrowing relatives. I have never in my own practice failed to put an end to stertor by position and management.

CASE 7.—At a medical meeting in May, 1862, after urging my views on stertor, the late Mr. Francis of Boughton stated that he had just left an old lady dying from apoplexy who had been in a state of stertor for many hours. At the November meeting in the same year he informed us that the old lady was still alive and well. On his return home in May he found her just as he had left her, dying, as he believed. He changed her position, the stertor ceased, and she gradually but perfectly recovered.

CASE 8.—The late Mr. Eustace Carver of Melbourne, a former house surgeon at the Middlesex Hospital and Nottingham Hospital, and a careful observer, was called to an aged patient who was in deep stertor and moribund. Life was evidently more a question of minutes than of hours. The position was changed, the stertor ceased, and the old gentleman lived for nine months.

Many cases have demonstrated that as power returns to the brain the pneumogastric nerves and probably also the sympathetic nerves regain their power and effusion into the lung ceases; and, moreover, it has been clearly shown that the lung is not injured by remaining inactive and filled with mucus for a long period. The consideration last mentioned induced me to adopt a lateral position in all condition of the lungs in which much mucus was secreted.

CASE 9.—In April, 1866, a little child, three months old, after having suffered from a slight catarrh for a few days, was seized with difficulty of breathing at night. When I arrived in the morning the child was livid, the eyes were sunken and half closed, and the pulse was remarkably slow, feeble, and irregular. The child breathed with great difficulty and had a loose mucous cough, feeble and ineffective. The quantity of mucus in the chest was so great that the child could not inspire and appeared to be dying. The patient was turned on the right side, ammonia was applied to the nostrils, and 10 drops of brandy were administered every quarter of an hour. On the following day the child breathed with greater ease, the expression had improved, and the pulse, though still slow, had a little more power. The air now entered the left side freely and the râles were few; there was no breathing at the right side. The child gradually recovered, but for several days there were bronchial breathing and bronchial voice on the right side. Before the child was turned on to the right side there was no difference on auscultation between the two sides.

In bronchitis generally, and especially in the bronchitis of the old, I endeavour to leave one lung free for breathing, and then, as vital power returns, the position is gradually changed. In the convulsions of children there is often a large flow of saliva and secretion into the bronchial tubes. This becomes immediately churned into foam and greatly impedes respiration. In the lateral position all this foam drains away, the breathing is freed, and recovery begins. In epilepsy the fit will often cease at once by removing stertor, but here it requires a little more management than placing the patient on his side, for the spasms of the mouth, tongue, and fauces require opposing by various mechanical contrivances

CASE 10.—In May, 1866, I was sent for to a phthisical patient who was said to be dying from hæmorrhage. I found him lying upon his back, partially elevated by pillows, and apparently breat[illegible] his jaw dropped. He made a few [illegible] large mucous râles were heard in the trachea. [illegible] could just be felt feebly flickering. He was immediately placed well over on the right side and ammonia was applied to the nostrils. A little brandy-and-water was introduced into the mouth, but there was no effort to swallow. A handkerchief was, however, soaked in brandy and a portion left in the mouth. The mouth and tongue were quite cold. In a minute or two the respirations became longer and air could be heard entering the uppermost lung, but none entered the lower. Gradually the râles diminished in the upper lung, air entered more freely, and the percussion sounds became more resonant. Consciousness, which had been utterly lost, gradually returned, and by the following morning he was perfectly himself and could have transacted any business. He lived for four days, breathing with one lung only.

CASE 11.—On March 22nd, 1894, I was hastily summoned to an apparently dying man. I found him lying on his back on the floor, motionless with the exception of occasional ineffectual gaspings; he was of a livid colour and his pupils were widely dilated. The feeble pulse could occasionally be felt but not counted. Three policemen and several coachmen were standing helplessly by. Observing blood on his clothes and about his mouth I opened the man's shirt and rapidly surveyed, percussed, and auscultated the front of his chest; finding more percussion dulness on the right side than on the left, and that no air was entering that lung, I gently turned him on to his worst side (the right), so as to leave the better lung free, and propped him up in that position with pillows. Each gasp now became a short gurgling inspiration, and signs of returning life began to show themselves by clutchings of the hands and spasmodic actions of the legs and an occasional moan. Some air entered the upper lung, the râles [illegible] the pulse became fuller and countable [illegible] left him in charge of Dr. E[illegible] a hypodermic injection of caffeine in sodium salicylate and an enema of two ounces of brandy. In half an hour Dr. Waggett reported that the man had quite recovered from present danger and was talking naturally to his friends. On the following morning I saw the man in consultation with Mr. Wise, his own medical attendant, and found him still lying on his right side, looking wonderfully better and quite himself; the temperature was normal and the pulse was 120. He was expectorating freely blood-clots and blood-stained muco-pus. There were very few râles to be heard in the upper (left) lung, and the air entered quite freely, so that as far as the danger from suffocation was concerned the man was safe.

This case recalled another, similar in its onset, different in [illegible] as a demonstration of [illegible] ent of such cas[illegible] ards in my student days the physician commented on the salient points of a case of phthisis in a young girl who was sitting dressed on the side of her bed. Ten minutes afterwards the physician was hastily summoned from the other end of the ward to see her again, and she was dead—at least, she had entirely ceased to breathe. She had been seized with hæmoptysis, the nurse had laid her on her back on the bed, and she had so become choked. At the necropsy large coagula were found in the trachea and bronchial tubes.

Lately I was taken by surprise in a case of hæmoptysis by a patient suddenly developing dyspnœa and cyanosis with starting eyeballs and dilating pupils whilst in the sitting posture. With sudden and violent effort he coughed up three or four large pinkish-grey masses similar in appearance to portions of emphysematous lung; on examination they proved to be coagula infiltrated with numberless fine air vesicles. It appears that in his terror of increasing his blood flow he had maintained the sitting position for some hours, and had studiously avoided coughing when he felt the râles in his chest, so that the small oozing from the affected (right) lung had gradually found its way into the sound lung, and had become inflated into large masses by the air vesicles which had slowly formed in the coagulating blood.

Death from tea in the lungs.—On Feb. 23rd, 1894, Dr. W. [illegible] the Clinical Society of London a case [illegible] diphtherial paralysis who had died [illegible] tea; after death one and a half ounces of tea were found in the bronchial tubes. Dr. White stated that after coughing for some seconds "the patient became very distressed in his breathing, exactly as if he had been suffering from asthma; there was at no time any evidence that the larynx was obstructed." The patient was dead in less than 10 minutes from his having taken the tea. The pulse was good to the end. It was assumed that the patient had died from spasm of the bronchial tubes from the specific action of tea on the nerve centres; but may it not be assumed, with even more confidence, that the patient was practically drowned with tea? One and a half ounces were found in his trachea after death. This is a large amount, and probably during life it was larger—quite enough, when mingled with mucus and churned into foam, to obstruct the main bronchi and thus to cause fatal suffocation. At the same meeting Mr. Pearce Gould related a case of suffocation in a child with diphtherial paralysis. Tracheotomy was instantly performed and the child was turned over, whereupon the bread-and-butter which the patient had been eating ran out of the wound in a liquid form and recovery ensued.

Dr. Frederick Weber told me of a case of death from suffocation in consequence of milk having been inspired in a case of diphtherial paralysis, so that bland fluids such as water and milk will cause death when introduced into the windpipe; we need not therefore assume that the specific influence of tea had anything to do with the cause of death in the case above referred to. We know what horrible distress supervenes on even one of the large bronchi becoming suddenly plugged by a cherry-stone or by a pea. In cases of drowning the amount of fluid usually found after death might not amount to more than was found in the foregoing case. It must always be remembered that the introduction of any fluid excites mucous secretion which, with saliva, inspissates the fluid and gives rise to foam bubbles, more or less large, and these add greatly to the difficulties of inspiration.

From these points of view it is clear that cases such as these may be successfully treated either by turning the patient on to one side, as in the cases of hæmoptysis just related, thus freeing one lung and so giving time for the obstructed lung to relieve itself by expelling or absorbing the intruded fluid; or relief may even more quickly be given by placing the patient on his face and pressing or striking on the back to assist the expulsion of the tea. Independently of its effect upon stertor "position" has a direct influence in many conditions allied to the apoplectic, such as chloroform-poisoning, drunkenness, &c.; and I have observed that in cases of great exhaustion the change from the back to the side is accompanied by immediate and great relief; the breathing, from having been carried on with evident effort, has become at once peaceful and easy. During sleep, when the vital powers are resting, it is not the back but the side which is selected as nature's position; and I believe the explanation to be that on the back the diaphragm has to lift the liver and abdominal organs with each inspiration, whereas on the side—especially the right side—the liver lies practically on the bed and the diaphragm can do its work without oppression.

[illegible] conclusions which may, I think, be fairly [illegible]—1. That [illegible] forms I formerly defined. 2. [illegible] tor which [illegible] with the apoplectic state are [illegible] the mucous stertor. 3. That [illegible] their remote cause, are the [illegible] 4. That it is necessary [illegible] that side should not be changed, and that the paralysed side should be downwards. 5. That mucus and other fluids gravitate into and fill up the lower lung; and therefore that if the sides be reversed the mucus will find its way into the opposite lung. 6. That the fluid, crossing from the large bronchi of one lung to those of the opposite, becomes churned into foam and causes dangerous obstruction to the respiration. 7. That the lung, by remaining inactive and filled with mucus for a long period, is not injured. 8. That these principles apply to all conditions in which blood, mucus, or fluid exists in the lungs and also to all conditions allied to the apoplectic, whether there be mucus or not. Finality in medicine never has, and probably never can, be reached. As the environments of man change so do his developments, both moral and physical; and the same may be said of all animal nature. We have, however, still left to us the first principles of the great laws of physics always at hand to apply to those changing conditions to which I have referred, and the object of these lectures has been to demonstrate to you many ways in which they can be practically applied to the relief of suffering humanity.

A CONTRIBUTION TO THE PATHOGENESIS OF CANCER.

BY JOHN MARNOCH, M.A., M.B., C.M. ABERD.,
SURGEON TO THE ABERDEEN ROYAL INFIRMARY.

IT is certainly impossible to examine an epithelioma without being struck by the fact, for long well known to pathologists, that the epithelial cells distending the alveoli are identical in appearance with the epithelial cells in which the morbid process began; and, further, that the epithelial elements in the secondary tumours, though far removed from the site of the primary tumour, are identical with the parent epithelium. Here, then, the law prevalent in mammals that epithelium covers exposed surfaces is infringed. The cells leave their natural habitat and wander into and live amongst the subjacent fibrous and other tissues of the mesoblast. Not only so, but the delicate balance between waste and repair is disturbed and proliferation takes place in excess, resulting in tumour formation. If, then, in epithelioma, cells which are indistinguishable from the parent epithelium live and multiply in the tissues of the mesoblast, the interesting question presents itself to consideration—namely, Will the normal skin epithelium when placed under similar conditions continue to grow, and if it does so, what will the relationship of the growth be to cancer? This question, and many closely allied to it, have engaged the attention of pathologists ever since the structure and development of cancer have been made objects of study. Thus, why does epithelium tend to cover the surface of the body and not dip down into the underlying tissues? This has never been satisfactorily explained. Then, again, why does it not tend to cover an indolent ulcer? Why does it accumulate in a mass at the edge and penetrate to a certain extent down amongst the sub-epithelial fibrous tissue? What is the meaning of this? Possibly it is because the surface of the ulcer is formed by exposed fascia, tendon, &c., covered by sloughing material. Whenever the slough has been removed by surgical treatment and the surface covered by young connective tissue with vascularity then the epithelium tends to run over instead of accumulating at the margin. There must be a proper young connective-tissue basis before the epithelium spreads, and all surgical treatment aims at stimulating the surface of the ulcer so as to produce this. Then, and only then, as a natural consequence the callous margin disappears and the epithelial growth is directed over the surface. So long as this young connective-tissue basis is absent the epithelium has no tendency to run over the abraded part but accumulates in a hard callous mass at the edge, penetrating to some extent the fibrous tissues beneath. This penetration, however, is more apparent than real, because the granulation tissue at the margin tends to sprout out through the callous mass, giving the appearance as if the accumulated epidermis had penetrated further than really is the case. Even here the penetration is comparatively slight and not such as one finds in an epithelioma of the skin. Not only will the epidermis at the edge run over this young connective-tissue basis once it is formed but pieces of epidermis taken from a distance, as in the skin-grafting of Reverdin and Thiersch, will also take hold upon it and grow. Again, in healing by first intention one frequently sees a piece of epithelium buried in the young cicatrix, but here there is good reason to believe that as the cicatrix increases in consistence it vanishes and becomes absorbed. Moreover, this appearance of an island of epithelium being buried is sometimes, at all events, fallacious for the reason that in cutting through the skin perpendicularly in making a microscopic section a portion of what is in reality a peninsula of epidermis is lopped off and in a single section gives rise to the appearance of an island of epidermis separated from the parent mass on the surface.

Among surgeons it is a pretty well-recognised fact that cancers of the skin are apt to form in old cicatrices. Even granted that this is so there is still wanting an explanation of how these tumours originate. Is it that a fragment of epidermis during the process of healing has become separated from that which covers the surface of the body generally and begins to grow on its own account and gives rise to a cancer tumour? Or may it not be, if we accept the parasitical origin of cancer, that the epidermis so buried has had in contact with it some parasite living on the surface of the skin which sets up the epithelial stimulation?

On these matters we are as yet completely in the dark, but so far as our knowledge at present goes the trend of opinion seems to favour the notion that normal epidermis, when separated from its proper nidus as an investing layer for the surface of the body and other exposed surfaces and buried deeply in tissues of mesoblastic origin, has the tendency to die and to become absorbed. This has been the current opinion of pathologists for many years past, but as all such matters are dependent for their refutation or verification upon experiment it is only natural that those who have been interested in the subject should have looked forward to evidence *pro* or *con* of this nature. Such experiments, although as yet not very numerous, have been performed abroad, and also to a certain extent in this country, with somewhat varying results. Kaufmann[1] in 1884 made a number of experiments upon the embedding of skin with a view very much similar to my own—namely, that of ascertaining whether epidermis when placed deeply in the tissues underwent any proliferative change comparable to what takes place in the case of a skin cancer. His most important experiments were made on the combs and wattles of fowls, such being selected on account of the absence of hairs on their surface or glands in the substance. The above structures are of the nature of erectile tissue, the blood-vessels being very large, somewhat cavernous and very numerous, and from a close inspection of them he was able to verify what is generally held to be the case—namely, that they are devoid of glands. His experiments consisted in circumscribing an island of skin surface by a continuous incision, raising flaps on each side and stitching them together over the island of skin. He made a large number of experiments and examined them at different times, the general result being as follows. The submerged epidermis began to grow apparently quicker than that of the flaps covering it and rose up at the margin so as to form a hollow structure into the opening of which there spread a quantity of young connective tissue and blood-vessels. The cavity in course of time closed so as to form a hollow tumour-like structure having very much the appearance of an atheroma cyst. The resemblance was rendered all the more striking by the epithelium on the inside of the cyst desquamating and forming an atheroma-like mass. The cyst lay embedded in the tissues and did not form any connexion with the epidermis of the flaps. The epithelium forming its wall did not die but continued to grow until the cyst-like cavity was completely closed. Thereafter, after a matter of 210 days, it appeared to remain stationary. Round about the cyst-like structure numerous giant cells formed, very much as they do round foreign bodies introduced into subcutaneous tissues. From minute examination he was convinced that these giant cells had no connexion whatever with the epithelium either of the island of skin or of the investing flaps, and he is inclined to trace the formation of some of them at least to the endothelium of the blood-vessels. Most of the giant cells were inclosed singly in a circumscribed space lined by cells of small size; others, however, were arranged in groups within a space lined by cells of small size, and in the centre of this aggregation of giant cells there was a channel-like lumen. These collections of giant cells he traces to the blood-vessels of the part and is perfectly clear that they were not the offspring of the epidermis anywhere in the neighbourhood.

The chief points of note in these experiments were in the first place that the submerged epidermis did not die, and in the second place that it tended to form an atheroma-like cyst which apparently in course of time came to lie as an inert tumour in the part in which it had been embedded. He also made similar experiments with the skin of young dogs but was apparently less successful with these, most of the wounds having suppurated.

[1] Ueber Enkatarrhaphie von Epithel; ein experimenteller Beitrag zur Entstehung der Geschwulste, Virchow's Archiv, Band xcvii., p. 236.

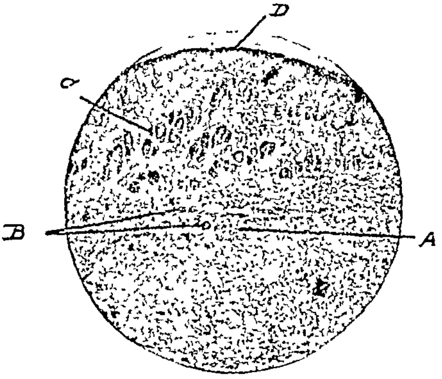
Chronic irritation seems undoubtedly to be a factor in the etiology of cancer, for it is a matter of everyday clinical experience that common sites of cancer in the human body are parts which are liable to frequent mechanical irritation. Then, again, the effects of chemical irritants in the production of malignancy is seen in the cancer of paraffin and tar workers. D'Arcy Power[2] investigated the effects of chronic irritation upon living tissues, more especially epithelium. His method of procedure was to irritate for a considerable period by the application of iodine liniment the mucous membrane of the vagina and then to observe the changes produced. The animals he utilised were rabbits, guinea-pigs, and rats, and the interest of his experiments lies in the fact that he was able to prod [illegible] respects those seen in [illegible] were mostly of the natur [illegible] such as vacuolation and œdema, while cell-nest formation was also observed. *In the case of a guinea-pig, after irritating* the vagina for some time, he found a lumbar gland enlarged which on section presented appearances almost of an endothelioma.

Acting on a particular theory as to the origin of cancer Beatson[3] instituted a number of experiments with the view of ascertaining whether the epithelium of the ovary and testicle of rabbits would proliferate when transplanted into other tissues or when inoculated with cancer from the human subject. In no case, however, did he meet with a positive result, the transplanted tissues being completely absorbed.

The object of my own experiments was to put to the proof what has been asserted—namely, that epithelium will not grow when taken from its natural site and buried deeply in the tissues, more especially those of mesoblastic origin, or in the various cavities of the body. In respect of the line of these experiments no doubt they have been anticipated to a certain extent by those of Kaufmann and others, but though the facts ascertained in these previous experiments were, so far as they went, convincing, yet they lacked confirmation, and it was partly with a view of verification and partly with a view of extending them that I undertook the present research. In Kaufmann's experiments the method of procedure was chiefly, as above said, that of covering an island of skin still retained in its natural position as regards the subjacent tissues by two flaps of skin raised up on either side of it. In this respect the experiment is less crucial than when the epidermis and other layers of the skin are detached from their natural site everywhere, except at one side which is held in connexion with the surrounding blood-vessels, and are then buried in the subcutaneous tissues; still less crucial than when the skin is completely detached from its surroundings and buried deeply in a tissue of which it is not a constituent part. T[illegible] were guinea-pigs and rabbits, s[illegible] paratively young. They were anæ[illegible] er and thereafter the area to be operated on was shaved and thoroughly disinfected and the operation was conducted with strict antiseptic precautions throughout. Collodion and absorbent wool after the application of spirit and ether were used as a dressing and the healing in all cases was by first intention, the animals remaining in good health. In preparing the sections afterwards, the tissues were dehydrated and then embedded in celloidin and cut either in a Schanza or freezing microtome in the usual way. The stains employed were logwood and eosine.

Experiment No. I.—Incisions were made through the skin of the abdomen of a guinea-pig, mapping out an ellipse about half an inch long and a quarter of an inch wide, and thereafter the edges were raised up so as to form flaps and united by sutures over the ellipse, so that it came to lie in the subcutaneous tissue under a linear wound. In such respect this was a repetition of Kaufmann's experiment. At the end of 14 days the animal was killed and a quadrilateral part of the whole thickness of the abdominal wall inclosing the wound and buried skin was cut out. In this case sections were made at right angles to the linear wound above mentioned. The flaps had united by an extremely fine cicatrix depressed at the immediate point of union as in ordinary healing of a wound by first intention. The epidermis was at the point of union very little if in any degree thicker than the epidermis of the surrounding parts. *The union, in fact,* seemed to be typically that of first intention. The cicatrix uniting the flaps was so fine that it could hardly be traced, a few spindles running downwards in a somewhat irregular fashion being all that indicated the line of union. As regards the portion of skin which was buried beneath the flaps taken from either side, the greater part of it seemed to have vanished. The epidermis had completely gone and the only portion that seemed to be left was that which corresponded with the corium (Fig. 1, *a*). This was densely infiltrated with spindle-shaped fibroblasts and was united to the superjacent flaps by a layer of cicatrix in which the connective-tissue cells were still more abundant than in the corium, some of them in the round stage, some elongating into spindles. Chiefly within this cicatrix uniting the remains of the buried piece of skin, but partly in the remains of the skin itself there were numerous sections of hairs to be seen evidently in process of absorption (Fig. 1, *b*). They appeared translucent and somewhat shrunken and their outline in many cases was irregular. The fact of many of these lying in the cicatrix between the embedded piece of skin and the flaps embedding it would seem to show that considerable absorption not only of the epidermis but also of the subjacent corium had taken place. In fact, the part of the skin left seemed to be the deepest layer of the corium and this again was attached to its subcutaneous fat tissue in a natural fashion. Running through the above-described cicatricial tissue, uniting the under surface of the *united flaps to the upper surface of the embedded* piece of skin, there was a fair number of capillary blood-vessels engorged with blood. There was no evidence of giant cells and in the remnants of the embedded piece of skin the skin glands were either absent or in process of absorption. The subjacent parts seemed to have undergone very little alteration farther than there being rather more cellular material round the blood-vessels and in the lymphatic spaces.

FIG. 1.



(*a*), Remains of corium densely infiltrated with fibroblasts and containing numerous sections of hairs (*b*) in process of absorption; (*c*), sections of normal hair follicles of flaps; (*d*), epithelium of superjacent flaps. × 50 diameters.

Experiment No II.—The above experiment was repeated and the animal was killed after the same lapse of time. The appearances differed in no way from those just described.

Experiments No III., IV., V., and VI.—The same experiment was performed in four guinea-pigs which were killed after three, four, five, and nine weeks respectively. After three weeks the hairs of the buried ellipse were considerably less distinct than in the previous experiment; also the fibroblasts were less numerous and the young fibrous tissue was more abundant. After four weeks hardly any trace of the buried ellipse could be found at all, while after five weeks not a vestige was to be seen.

Experiment No. VII.—An incision was made through the linea alba of a guinea-pig and the abdominal cavity was opened. A piece of skin half an inch long and a quarter of an inch wide was detached from the abdominal wall and stitched to the parietal peritoneum with the epithelial side next the abdominal cavity. Three months afterwards the animal was killed and the abdomen was opened. No trace could be found of the transplanted skin and the internal organs appeared to be healthy in every way.

---

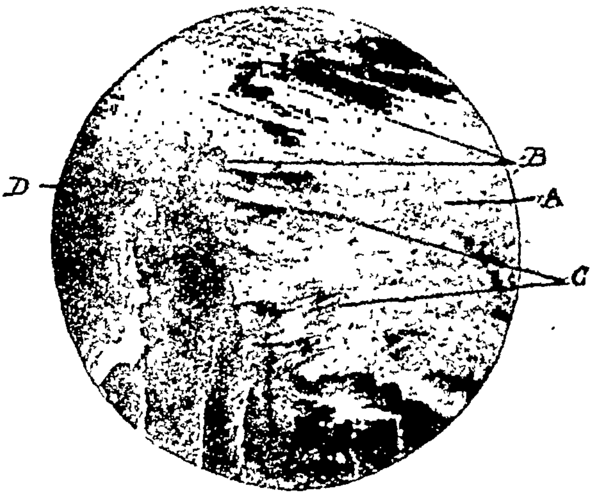
[2] Brit. Med. Jour., Oct. 14th, 1893.
[3] Ibid., Feb. 18th, 1899.

Experiment No. VIII.—From the abdomen of a guinea-pig a rectangular tongue of skin one inch long and half an inch broad was dissected up but left attached at one of its narrow ends. The skin under the attached end and for a little distance behind was undermined so as to form a small pocket in the subcutaneous tissue into which the dissected tongue mentioned was turned so that it came to lie under the skin with its epithelial side downwards. By making relaxation incisions the oblong gap left was closed, forming a T-shaped incision. After 14 days a square-shaped piece of the whole thickness of the abdominal wall containing the inverted skin was cut out and sections were made parallel to its long axis. Here, as in the case of the buried ellipse experiments (Nos. I. to VI.), no vestige of the buried epithelium remained. At the point where the skin turned so as to dip into the subcutaneous pocket the epithelial layer was well marked, devoid of hair follicles, and ran evenly on without dipping into the underlying tissues. Immediately under this the remnants of the rectangular tongue of skin presented appearances very similar to those seen in experiment No. I.

Experiment No. IX.—An oblong-shaped tongue of skin with its long axis at right angles to the linea alba was dissected up from the right side of the abdomen of a guinea-pig, leaving the base which was at the linea alba still attached. The abdominal cavity was afterwards opened beneath the attachment, the tongue of skin was turned in and attached to the parietal peritoneum on the left side by silkworm-gut sutures, so that it lay with its epithelial surface next to the intestine. The abdominal wound was then stitched up. Ten days afterwards the whole abdominal wall was cut out and the site of the tongue of skin was found covered with plastic exudate. The portion of tissue around and including this was separated from the surrounding abdominal parietes and sections were cut at right angles to the linea alba. Just where the tongue of skin ran through the abdominal wall to reach the peritoneum a small depression was noticed on the surface of the section. This depression was covered by epithelium and in the young cicatrix immediately below were one or two islands of epithelium, but on tracing the tongue of skin further on no epithelium could be seen, while the fibrous tissue stained well with eosine but failed to react to the logwood, an appearance which probably indicated that the tongue of skin was dead or in process of absorption. The hair follicles were fairly well marked and retained to some extent the logwood stain. The vessels did not appear to have been unduly constricted. The change that had taken place in the tongue of skin seemed to have been alike with that which occurred in Experiments I. to VI. where the skin was not detached but simply embedded in an abnormal situation.

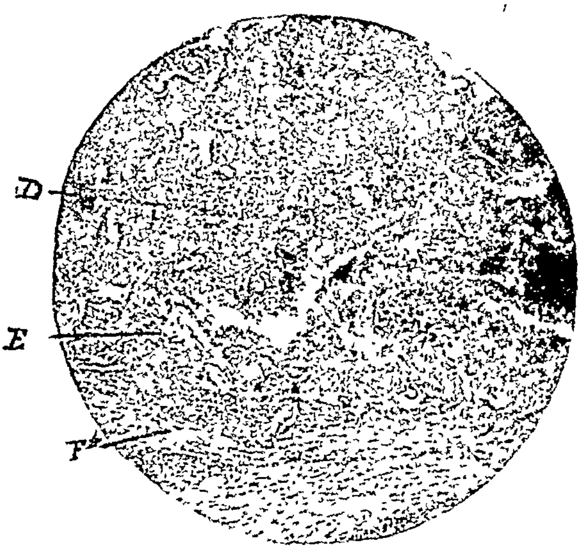
Experiment No. X.—An incision through the skin and subcutaneous tissue was made over the most muscular part of the hip of a rabbit and an inter-muscular septum was found. This was penetrated so that the adjacent muscles were separated for a short distance. A small compartment was thereafter cut out of the muscle on one side and into it was placed a piece of skin detached from the hip, about three-eighths of an inch square. The piece of skin was rolled in a section of sterilised sponge and held together by fine catgut. The inter-muscular space and the skin incision were closed. Four and a half months after operation the animal was killed and on exposing the inter-muscular septum the sponge with its contents inclosed in the compartment could be felt as a hard round nodule covered with some fat. A piece of muscle with the nodule in its centre was cut out and sections were made. The sections showed a central oval portion, evidently the nodule with its sponge, &c., and an outer surrounding area. The latter was seen to consist of muscle-fibres cut in various directions. Immediately within this and encircling the oval portion a thin layer of fat was found. The nodule consisted of a small central part stained almost entirely with the eosine and a surrounding part deeply stained with logwood. The central eosine-stained part proved to be the buried skin (Fig. 2, *a*). This was found cut in various directions in different sections, but those in which the skin had been cut perpendicularly to its surface showed best what had happened. The line of demarcation between the epidermis and the subjacent corium (Fig. 2, *b*) was well marked, the epithelial remains being coloured deeply with the logwood but in a very diffuse fashion, while the subjacent corium had taken on the eosine stain alone. Running downwards into the latter were the remains of the hair follicles very indistinctly mapped out and with the stumps of the hairs still remaining in their centre (Fig. 2, *c*). Neither in the remains of the epidermis, the hair follicles, nor the subjacent corium were there any individual cells to be seen, clearly pointing to the fact that the piece of embedded skin was dead and undergoing disintegration. The superficial layers of epidermis were converted into a granular amorphous mass which coloured deeply with logwood, but in which epidermic cells were indistinguishable. Immediately surrounding the skin and making up the rest of the oval nodule were to be found the branching fibres of sponge framework (Figs. 2 and 3, *d*). The interstices of its fibres were everywhere filled by a dense mass of amorphous caseous-looking material, except at the circumference of the nodule, where for a short distance this was penetrated by

FIG. 2.



Centre of nodule containing skin (*a*) (the light-coloured part to the right) showing the line of demarcation (*b*) between the epithelium and the subjacent corium penetrated by bundles of hair stumps (*c*) and surrounded by the dense mass of amorphous caseous-looking material with sponge framework (*d*). × 50 diameters.

FIG. 3.



Periphery of central oval portion showing sponge framework with caseous amorphous-looking material (*d*) penetrated for a short distance by fibroblasts (*e*) with bundles of newly-formed fibrous tissue (*f*). × 50 diameters.

great numbers of round and spindle-shaped cells with corresponding single nuclei, evidently fibroblasts (Fig 3, *e*), with here and there bundles of newly formed fibrous tissue and occasional capillary blood-vessels (Fig 3, *f*)

Experiment No XI—This experiment, which was performed also on a rabbit, was precisely similar in detail to the previous one, but the animal was killed two and a half months after operation The appearances differed in no respect from those of the previous experiment except that the layer of fibroblasts at the periphery of the nodule was not so deep The epidermis in this experiment also was represented by an amorphous granular mass

These conclude my experiments with natural epidermis, and while making them, having recently excised an epithelioma of the cheek and had an opportunity of getting some cancer tissue from the bladder of a living subject, I thought it might be opportune to transplant these under the same circumstances as in the foregoing experiments where the skin was completely detached As is well known, cancer transplantation experiments from the human subject have been made to the lower animals in numerous instances previously mostly with negative results, but as the results in this case agree so closely with the other results I have obtained with normal epidermis perhaps it may be of interest to quote them in this connexion.

Experiment No XII.—An incision was made through the skin of the back of a guinea-pig and a small pocket formed in the subcutaneous tissue *Into this a small piece of a* recently excised epithelioma of the cheek was placed and the wound stitched up The animal remained perfectly well and two months after the experiment it was killed and the site of operation was examined No trace, either naked-eye or microscopic, could be found of the epitheliomatous tissue, the scar being perfectly healthy, as were also the internal organs

Experiment No XIII—A portion from the centre of a cancerous nodule taken from the bladder was buried in the subcutaneous tissue of the abdominal wall of a guinea-pig with the same result as in experiment No XII

Remarks—The results of my experiments, it will be seen, although conceived on the same lines as those of Kaufmann, are in some respects directly opposed to those obtained by him As previously detailed in the synopsis given of his experiments, the buried epidermis even after a term of 210 days continued to live and became converted into a cyst-like tumour On the contrary, in my own case I found invariably that the epidermis dies, quite irrespectively of the skin being entirely separated from its normal surroundings and its natural blood-supply, or whether the blood supply is still continued This seems a very curious antagonism in the results and how it is to be accounted for is not quite clear Quite possibly the epidermis of the cock's comb or wattle possesses greater power of vitality than the ordinary epidermis, otherwise it is difficult to explain the discrepancy which prevails in the results of his experiments and my own So far, at any rate, both sets of experiments seem to be at one in this respect, in that they show that when epidermis under varying conditions is transplanted into or buried beneath a tissue of mesoblastic origin even though it may continue to live it does not manifest the properties of a cancerous growth Even in the cyst like tumour which was formed in Kaufmann's animals the character of the growth was essentially what might be called homologous In none of his preparations did he discover a heterologous breaking up of the epidermis and its invasion of the tissues of which it is not a normal constituent So far as these two sets of experiments point the lesson we are therefore bound to conclude that a cancer tumour is not merely epidermis which has found its way deeply into the underlying parts, but that the epithelium entering into the composition of these tumours must for some ulterior reason be endowed with specific properties, not merely of proliferation, but of burrowing into foreign parts What this particular property depends upon, whether it is parasitical or not, remains as yet, we may say, in great part unsettled On the one hand, we have the allegation made by Lack[4] that, in the case of the epithelium of the ovary at any rate, all that is necessary in order to cause it to exhibit the properties of cancer epithelium is to set it free in a cavity such as the peritoneal On the other hand we have authors such as Plimmer[5] asserting quite as *confidently that the disease is a* parasitic one, that the parasite can be cultivated artificially, and that when it is introduced into the system of a suitable animal it occasions a tumour at least of epitheliomatous nature In how far we are to conclude for the one view or the other or whether the truth may reside in either is probably in the minds of most pathologists and practical surgeons as yet of the nature of a *quæstio vexata* It has been asserted by Shattock[6] that cancer is a disease of rabbits to which they are subject naturally, and so far as I am aware Lack has not succeeded in repeating successfully his extremely interesting experiment The coincidence of the outbreak of cancerous disease with the scraping of the ovary and transplantation of its epithelium to the peritoneum seems on the face of it a very remarkable one, and quite possibly it is an experiment which might succeed in one out of a large number of instances, but until *this experiment* or one allied to it has been repeated successfully most pathologists and surgeons will I am afraid, be inclined to hold the case *sub judice*

My experiments have a further important bearing on the whole subject of epithelial transplantation and proliferation when taken in connexion with those of Ljunggren and Wentscher Ljunggren[7] preserved carefully sterilised patches of human skin in sterile ascitic fluid and to his surprise found that even for as long as three months the cells of the deeper layers showed well stained nuclei and good protoplasmic structure Not only so, but he also discovered the very remarkable fact that if these pieces of skin, after being retained in the sterile *ascitic fluid*, were *transplanted to a* granulating surface that not only did they become united to it, as might have been the case with many bodies *destitute* of vitality, but, as proved by microscopic examination, that the pieces of skin continued to live, took hold upon the part, and became incorporated with it Strange as such a statement may appear to any biologist and sceptical as one might be as to the truth of Ljunggren's allegation, these experiments were very shortly afterwards quite independently not only corroborated but extended by Wentscher[8] Briefly stated, the most important points in Wentscher's extremely interesting paper are that he excised patches of skin ("Thiersch'sche Läppchen") from the living subject, either the subject of experiment or *derived from* another person, in their entire thickness and including a small amount of subcutaneous fat tissue The pieces measured six by four centimetres or thereabouts and immediately after being excised (by preference from the skin of the leg) they were treated by one of two different methods Either they were placed in aseptic 0 6 per cent solution of common salt, antiseptic precautions being used all through the course of the operation, or they were merely hung up by means of a silk thread in a sterile bottle plugged with cotton-wool In either case the pieces were left for a varying time, up to 22 days at the longest In the case of the piece of skin hung up in the sterile bottle the surface had become to some extent *mummified, dry, and of* a brownish colour, and on the day previous to transplanting it it was placed for a matter of 24 hours in the above salt solution, by which time it had again swollen up and resumed in great part its normal aspect. These pieces of skin, treated by the methods just detailed, were then placed in the midst of a healthy granulating surface which as far as possible was rendered aseptic but previously to the application of the graft a piece of the granulating surface was completely excised either corresponding to the dimensions of the graft or somewhat smaller, in fact, in some of the experiments the graft overlapped the edge of the wound Extraordinary to relate, it was found that after a period of from three to *nine days the grafts were found* to have formed an attachment to the underlying surface The superficial horny epidermis tended to desquamate, leaving, however the underlying rete Malpighii, which assumed a peculiar transparent and glossy appearance in contrast to the appearance of the surrounding skin As soon as the graft had taken hold upon the surface pieces were excised from the centre for the purpose of histological examination and, curious to relate, not only was the epidermis found to retain evidence of vitality in the staining of its nuclei and preservation of its protoplasm but was in process of active mitotic division Vessels very soon penetrate into the graft and as soon as they reach the papillary layer of the cutis vera this activity of the epidermic cells becomes manifest. In those experiments where the graft overlapped the edges of the wound these edges curled up and apparently died, but the portion which was placed in contact with the area from which the granulation tissue had been excised continued to live, became attached to and completely incorporated with it, and in this way brought about the healing of the wound. The immersion in salt solution of the patches or the drying of them previously to transplantation had little or no effect in destroying the vitality of the epidermis even after so long a time as something like three weeks.

[5] The Practitioner: Special Cancer Number, April, 1899

[6] *Brit Med Jour* Jan 20th 1900 p 136 A Criticism of the [illegible]

[illegible] from "Om Hudepitelets [illegible] na Bibehalla lifvet [illegible]

[illegible] zur Allgemeinen Patho [illegible]

In my own experiments the epidermis was placed under conditions which might be reckoned the most suitable not only for its continuing to live but for reproducing itself. Yet as the account of them conclusively shows, in no case, modify the experiment as I chose, did the epidermis continue even to live beyond a few days, and in some instances after a matter of 14 days not only had the epidermis disappeared but even the true skin had almost entirely vanished. In fact, the whole skin graft had practically entirely disappeared. Apart from the drying and immersion in the various liquids quoted in Ljunggren's and Wentscher's experiments the main difference in their experiments as compared with mine was the fact that the one set of grafts was placed upon an exposed surface while the other set was buried deeply in the underlying tissues or placed in the abdominal cavity. What the difference in the result was due to, why the skin continued to live under such extraordinary circumstances and became incorporated with the surrounding tissues, and why in the other case it invariably died and was absorbed, appear to me a complete mystery. We are almost forced to believe that the exposure on the surface, whatever the influence be which is brought to bear upon the epidermis, is the main factor which determines whether transplanted epidermis will live and grow or not. In Wentscher's experiments it was found that certain islands of epidermis became separated and pushed out from the glands contained in it, but apparently these tend either to come to the surface or die out. Even at some parts of the epidermis thus grafted the rete Malpighii was found to extend downwards in processes for a certain distance, but in none of the cases is it recorded that anything like a cancer tumour resulted. These appearances were nothing more than one sees so frequently in epidermic surfaces under the influence of stimulation.

In conclusion, I have to thank Professor D. J. Hamilton for very valuable help during the above research. I am also indebted to Dr. J. S. H. Walker and Dr. G. M. Duncan for the micro-photographs.

Pathological Laboratory, Aberdeen University.

A CASE OF TUBERCULOUS ISCHIO-RECTAL ABSCESS AND FISTULA, WITH LARDACEOUS DISEASE OF THE KIDNEYS.

By CECIL H. LEAF, M.B. Cantab., F.R.C.S. Eng.,
ASSISTANT SURGEON TO THE CANCER HOSPITAL, BROMPTON, AND TO THE GORDON HOSPITAL FOR DISEASES OF THE RECTUM;
AND
H. W. SYERS, M.A., M.D. Cantab.,
PHYSICIAN TO OUT-PATIENTS TO THE GREAT NORTHERN CENTRAL HOSPITAL.

A man, aged 32 years, was admitted to the Gordon Hospital on August 29th, 1900, complaining that he suffered a great deal from constipation. He said that from the constant straining efforts which he felt compelled to make he would frequently pass blood which would be followed by diarrhœa or a discharge of mucus and a feeling of soreness. For the last two years the symptoms had been getting worse; the pain on defecation had been intense and the discharge of mucus and diarrhœa had become constant. The patient had been in India for 10 years. Though no definite history of syphilis could be elicited there were two somewhat suspicious-looking scars in the skin over the right side of the liver. He had never had dysentery. An abscess in the right loin had been opened, the scar from the operation being apparent. In both groins there was an enlarged gland. On the left side this was partly caseating, the bluish skin over it being undermined; on the right side, though there was no actual discharge, the skin was adherent, and the gland looked as though it would break down on the slightest provocation. The patient was evidently a tuberculous subject.

The operation was performed on Sept. 4th, when a large ischio-rectal abscess on the right side was found which was opened and enlarged and the cavity thoroughly scraped. A small fistulous track ran upwards from the cavity to the interval between the two sphincter muscles on the right side. This was laid open in the usual way. Immediately in front of the lower end of the coccyx a somewhat ill-defined thickening of about the size of a hazel nut could be felt in connexion with the walls of the rectum. It was at first difficult to determine whether this thickening had any connexion with the abscess cavity or fistula mentioned above, but eventually it was found possible to pass a probe from the internal opening between the sphincters into the thickening. The intervening track was found to be directed from the right to the posterior aspect of the bowel. This was thoroughly divided with Allingham's scissors, and in so doing the whole of the internal sphincter muscle was divided. The thickening in front of the coccyx was evidently an old abscess cavity, the walls of which had become much indurated. There was little bleeding at the operation. The wound was carefully dressed from the bottom with wool wrung out in a perchloride of mercury lotion (1 in 4000).

On Oct. 13th the wound was looking healthy, though there was still a large unhealed surface over the site of the fistula. The patient, who had previously suffered from complete incontinence, was now able to retain his motions for a short time. On the 20th the contraction of the sphincter muscles was good, and the motions could be retained for the greater part of the day. The evening temperature ranged from 99·4° to 100° F. The wound, which was not yet healed, was dressed with nitrate of silver (four grains to the ounce). The patient subsequently had diarrhœa, and on the 30th the granulating area, though a little less extensive, was not so healthy. The evening temperature remained the same. On Nov. 27th the patient was examined under an anæsthetic, when the ulceration over the site of the operation wound was found to extend upwards for one and a half inches. The patient left the hospital on the 29th having been directed to keep the bowels open, and to have the ulcerated surface dressed twice a day with calomel ointment. On Dec. 14th considerable œdema of the ankles and legs was noticed. The urine was quite clear, its specific gravity being 1015; it contained nearly a quarter of albumin. On Jan. 1st, 1901, the œdema became general and extended to the face; the eyelids were not much swollen. On the 12th the œdema had entirely subsided, except from the genitals. The urine was still clear and contained about a quarter of albumin. The ulceration in the rectum had almost disappeared, but there was a slight tendency to constriction; the forefinger, however, could easily be admitted. There was no pain on defecation and no incontinence. During February and the early part of March the patient was able to be up for the greater part of the day, and he had no trouble whatever with the rectum. On March 23rd there was a slight discharge from the rectum but no pain on defecation and no stricture. On April 20th the patient complained of intolerable itching all over the body. The scrotum was found to be ulcerated and the left epididymis swollen and painful. The abdomen was large and the œdema about the ankles and knees was still apparent. On May 11th the œdema became again more marked and the abdomen was larger and a little fluid was present in the abdominal cavity. The urine still retained the same characteristics; its specific gravity was 1015, it was quite clear and absolutely free from casts, and on boiling it became nearly solid from the large amount of albumin present in it. On the 22nd, after 10 days' complete rest in bed, the œdema had again entirely disappeared except from the scrotum and penis, the discharge from the rectum had ceased, there was no pain on defecation, and there was no stricture.

Remarks.

With such signs of tuberculous disease it can well be imagined that the patient was not the most favourable subject for operation, yet in spite of this the condition of his rectum has been much improved. Except for a slight discharge—which only comes on after he has been walking too much—he suffers no inconvenience, though at one time it seemed almost certain that a stricture would be formed, but this has been prevented by the daily passage of the finger. Another point worth noticing is the fact that though the internal sphincter muscle was completely divided, the patient has now entire control over the bowel, the contraction of both sphincter muscles being extraordinarily good.

From the medical aspect there can, we think, be no doubt that in this case the symptoms were due to the presence of lardaceous degeneration of the kidney. The marked œdema, the abundant urine of clear and non albuminous appearance, the enormous amount of albumin, together with the total absence of casts all point in this direction. Further, the presence of the more usual forms of nephritis is excluded by the normal condition of the heart and vessels. *Reduplication of the first and accentuation of the second* sound were altogether absent, and there was no hypertrophy of the left ventricle. The pulse, too, was very far from presenting the qualities found to characterise chronic renal disease.

The case seems to be an important one in the light of the difference of opinion which exists concerning the nature of the renal lesion which accompanies tuberculosis. Quite recently Dr Landouzy and Dr Bernard[1] published a paper in which they upheld a contention that tuberculosis, pulmonary and other, acts on the kidneys through the effect of the toxins which appertain to the activity of the tubercle bacillus. These authors maintain that the bacillus has no direct action on the kidney structure, but that a chronic inflammatory process is engendered by the "toxin" of the bacillus which eventuates in a chronic parenchymatous nephritis. Quite opposed to this view is that of Dr A. Brault[2] who strongly criticises the argument of Dr Landouzy and Dr Bernard. He says that there is no evidence whatever of the existence of such a form of nephritis as that described by the writers just named. Dr Brault attributes all the symptoms referred to by Dr Landouzy and Dr Bernard as being the result of the presence of amyloid disease of the kidney. He points out, further, that the so-called "large white kidney" of old days is neither more nor less than this same lardaceous degeneration of the organ. We are in entire accord with Dr Brault on this subject. We do not accept the arguments which would attribute to tuberculosis of the lungs and other organs the power of initiating kidney changes which are *sui generis* and are due to the action of a "toxin" of which nothing is known. But as for the "large white kidney"—a term happily now nearly extinct—we have no doubt at all that it is merely a more or less marked form of amyloid renal disease. It will be *noticed that in the present case* the symptoms are just those which were formerly attributed to the presence of the "large white kidney"—viz., large quantities of urine and of albumin, much œdema, and considerable pallor. The presence of tuberculous disease no doubt accounts for the lardaceous degeneration of the kidneys, a condition comparatively rare and one which has given rise to great errors, both as regards pathology and diagnosis. For this reason we think that the present case is one of some importance as elucidating a form of renal disease which has given rise to much misconception.

[2] Ibid April 6th, 1901

INFANTILE MORTALITY AT BATH.—At the meeting of the Bath Sanitary Committee held on June 24th the medical officer of health reported that he had caused leaflets *to be distributed* in regard *to the treatment* of children in the city. Dr Symons added that 31 children had died from diarrhœa in 1898 and 30 in 1899 whereas in 1900 only five deaths had occurred from the disease.

DISTRIBUTION OF CHARITABLE FUNDS.—The assistant commissioner of charity inquiries (Mr Cardew) has been holding investigations in connexion with the charities of villages near Devizes. At Rowde, one charity bequeathed in 1715 was stated to be disbursed in payments of 8*d* each to 492 applicants. Mr Cardew urged the adoption of some different method of distributing the money, such as contributing to a local hospital where the parishioners in need of medical and surgical treatment could receive treatment.

THE PHYSICAL CAUSES OF THE SLIGHTER FORMS OF MENTAL DEFECTS IN CHILDREN.[1]

BY FRANK M POPE, M D

IN 1899 the Elementary Education (Defective and Epileptic Children) Act was passed, entitled, "An Act to make better provision for the Elementary Education of *Defective* and Epileptic Children in England and Wales." This Act empowers school authorities (1) to ascertain what children in their district not being merely dull or backward and not being imbecile are defective—that is to say, what children by reason of mental or physical defect are incapable of receiving proper benefit from the instruction in public elementary schools, but are not incapable by reason of such defect of receiving benefit from instruction in special schools, and (2) what epileptics are capable of receiving benefit. The State thus did for mentally defective children what it had previously done for the deaf and dumb and the blind.

The duty of deciding as to what children came under the above definition was given to approved medical men, examination by whom was made compulsory, and the school age of such children was raised to 16 years. I was appointed to act in this manner for the Leicester School Board and have *in consequence* examined a large number of children. After doing this I looked up the literature on the subject, more particularly the work[2] and reports[3] referred to below, and Dr F Warner's article in "Allbutt's System of Medicine."[4] In the report of the Committee there is an immense mass of statistics, over 100,000 children of every degree of mental capacity having been examined. The direction the inquiry had taken was mainly that of observing the conditions of the children with regard to bodily development and defects. The former was in many cases found to be imperfect and the latter were frequent, and the conclusion sought to be enforced appeared to be that the physical defects and so-called abnormal nerve signs were on the whole an index of the accompanying mental defect if any. Abnormal nerve signs are the conditions of expression, tone of facial muscles, "position of hands," tremor, "response to action," and others, and the remark is made that observers in this field must depend for any good results on inspection mainly, this being thought to give better results than the appraisement of the mental deficiency by interrogation of the child. The physical defects to which the observers attached most significance were cranial abnormalities—large heads, small heads, cranial bosses (rickets), defect of forehead, frontal ridges, and head asymmetrical, defective ears (*external*), *palate*—high-arched V-shaped, cleft and others, defective nasal bones, and general debility. The correlation of these two classes of signs is made the criterion of mental defect. I reserve my criticisms on these reports till later, only remarking here (1) that Dr Warner acknowledges that some dull children have no defect and that some children with these signs are not dull, (2) that there is an underlying assumption throughout the report that these signs are those of degeneration, and (3) that Dr Warner says that these signs appear to be inherited. Their conclusions appear to be mainly that physical conditions are an index of mental ones, that both should be looked for, and that no risk should be run of neglecting children who exhibit defects. As a practical outcome of the Committee's labours the Act of 1899 was passed. I do not know *that one can blame these committees* for not having investigated the causes of such defects. If it was the case that they did not examine the children closely, as for cardiac defects and the like and that they were not supplied with family histories, it is obvious that they were not in a position to undertake the inquiry. Under the Act of 1899 the medical officers have the opportunities which were wanting to these committees. The parents are usually seen and the children can be closely and carefully examined. After making many such examinations it appears to me that it would be possible to inquire more closely into the pathological causes of the mental defects presented by the children with a prospect of arriving at some definite conclusions. I therefore undertook further inquiries into the subject, the results of which I here present.

[1] Thesis for degree of M D in the University of Cambridge.
[2] Shuttleworth Mentally Deficient Children second edition (Lewis, 1900)
[3] [illegible] a Study of the Mental and Physical Condi[illegible]
[illegible] London:
Macmillan, [illegible]

I have examined about 120 children in the schools of the Leicester School Board. These children were most of them already in the special classes for defective children, having been found, by the teachers in the first place, and by the inspector, a man of great experience—Mr. H. Major, B.Sc. Lond.—in the second, to be unfit for the ordinary school work. All children examined were admittedly defective mentally. Thus by rule of thumb the special class desired had been already weeded out and the medical examination could be directed to ascertaining if any were either mentally so deficient that it was useless to expect any improvement under education, or, on the other hand, if there were any whose defect was not marked enough to prevent their being placed in the ordinary classes. In most cases the mother and the teacher were present at the examination of the child, so that the family history could be inquired into, and cross-examination (which is most necessary) could be practised. When I found that it was possible that some light might be thrown on the etiology of these mental defects by the facts which I had ascertained by leave of the London School Board I obtained access to the reports of about 200 of the defective children in their schools, and the result of this examination is included with my own results. In addition, I made observations on 500 children in the upper fifth, sixth, and seventh standards of the Leicester board schools, with a view of seeing if any of the defects supposed to indicate mental deficiency were present in those presumably the brightest of the scholars. It was my original intention to have excluded what are usually termed imbeciles from my statistics, but I soon found that apart from the difficulty of drawing a hard-and-fast line between these and the simply defective cases it was probable that they differed only in degree from the milder cases, and the causes producing the defective condition were probably alike in all. A certain proportion of the imbeciles and idiots are besides excluded from most of the statistics by the separation of the hereditary from the non-hereditary cases. It seemed probable that some of the causes producing insanity would also operate in those minor defective mental states (of course, excluding causes such as intemperance, &c., acting in the lifetime of the insane person), and of these that heredity would be one of the most important. Maudsley[5] says of the causes of idiocy that many of them operate after birth; they are epilepsy, the acute exanthemata, perhaps syphilis, and certainly starvation, diet, and overcrowding. Shuttleworth gives an excellent *résumé* of the various factors of causation. I need not enumerate them, as I shall take his list as the basis of classification of my own cases (see also Ireland[6]).

Heredity.—In the insanity of adults, in idiocy, and in imbecility there is no doubt that one of the most important causes is heredity. If to those cases having a clear history of insanity in the family we add those having a clear history of epilepsy we get a considerable proportion of cases of mental weakness accounted for. These cases are also in the truest sense of the word hereditary, for we can hardly conceive of the transmitted defect, be it what it may, as anything other than one which is of the essence of the organism, and as being present in the germ or sperm cell, and hence not only as having been transmitted, but as being also transmissible to future offspring. The question of the part played by heredity in insanity has been often fully treated, and I therefore consider myself justified in excluding altogether from the scope of my inquiry, at any rate as far as numbers and conclusions arrived at from numbers are concerned, all cases where a clear family history of insanity or epilepsy in the family can be ascertained. I therefore allow that a percentage of perhaps about 30 of the cases of mental deficiency which are being treated in special classes are due to inherited defect from insane or epileptic parents, and I am only attempting to show the causation of the remainder (perhaps 70 per cent.). I have satisfied myself, as far as the cases which I myself have examined, that I have excluded heredity, but with regard to the London cases I fancy that the family histories were not complete in all instances. As, however, the exclusion of some hereditary cases will tell against and not for my conclusions, such accidental inclusion will really strengthen my arguments.

Development of brain.—I need not enter very fully into the manner in which the brain is developed. After the hind-brain, with its centres for respiration and circulation, is developed, great tracts having for their function the placing of the hemispheres and subjacent great ganglia in communication with the organs of special sense and the tactile sensory system have to be elaborated, and the great motor tracts placing the hemispheres in connexion with the locomotor apparatus have to be formed, and *pari passu* with these growths are built up the cerebellar and other controlling mechanisms. Lastly, in the cerebrum there appears to go on for the greater part of life a linking up of the higher centres, making certain paths easier and possibly, but not so certainly, other paths more difficult, for nervous impulses to traverse. For the proper working of even the very lowest degree of human intelligence a comparatively high development of the central nervous system is necessary. The sense organs must be developed and intact, their sensoria developed and intact, the efferent apparatus for expression, whether lingual or cheirokinæsthetic, developed and intact, and the connecting links, if not all completely developed, must at any rate be in a condition allowing of development. By the time a child has reached an educable age it is probable that little difference could be distinguished histologically between the brain of such child and that of a man aged 25 years.[7] It is obvious that in the course of the growth of such a complex organ the possibilities of interference with its proper development are very numerous and that such interference may take place at any time. We are familiar with teratological monstrosities in which the hemispheres are undeveloped, with idiots in whom we can find every variety of arrested development—brains with few convolutions, non-development of optic or auditory tracts, and the rare cases of non-development of the pyramidal tracts. Shuttleworth divides his cases into congenital and non-congenital, and places between these a mixed class which he terms "developmental." This is, of course, a classification of utility only. The defect arising from an injury to the fœtus by the mother falling down stairs is precisely comparable to that due to the child of a few months being dropped, and so is intra-uterine to extra-uterine small-pox. I propose, however, to follow him to some extent and to classify the causes of mental defects into ante-natal, natal, and post-natal causes.

General mental condition of cases examined.—The children whose examination forms the basis of these statistics varied considerably in mental power. Some, as has been stated, were imbeciles, but capable of speech and of some amount of education, and from these the gradation could be traced up to the child who after a few months' training in the defective children's class was able to join normal children of a somewhat younger age. Moral defect was uncommon among them and except in the hereditary cases it was not usual to find them troublesome to their teachers. Perhaps the best way to describe them is to say that before special training they are about equal mentally to children of the age of four or five years. They lack the power of concentration of thought and, as a rule, cannot reckon except in very low numbers. Their imitative powers are weak, hence they seldom write or draw well.

Method of investigating the causes of the mental defects.—A few words are necessary as to the method by which the assigned causes of mental deficiency were ascertained. Two returns on forms prescribed by the Education Department were filled up for each child, one by the teacher of the class in which the child was and the other by a parent and the teacher conjointly. The latter contains statements of age of parents, their mental condition, condition as to temperance, cause of death if not living, ages and states of health of living brothers and sisters, and causes of, and ages at death of, deceased ones; whether insanity, fits, consumption, or scrofula existed in the family; the time when the mental deficiency of child was first observed; the cause to which it is attributed, and other facts. Taking these as a basis, the mother in most cases, the father or other near relative in a few, was seen and questioned, especially as to the time when the deficiency was first observed and the causes assigned for it, and care was taken that at least no cause was put down as probable unless it had preceded in time the observed mental deficiency The mere fact of such a disease as measles being assigned by a mother as a cause was not thought to justify its inclusion unless it was expressly stated that the child was very seriously ill at the time or unless the complications or sequelæ of the disease—e g , long insensibility, aural or ophthalmic trouble—gave some colour to the assertion, and so with other assigned causes In most cases the mothers were intelligent women and it is difficult to see whose opinion could be taken in preference to theirs, as a complete medical life history written by a medical man was impossible to be obtained The mothers had no pre existing ideas on the subject, and I think I shall show that in most instances the causes which they assigned had much to do with the arrest of brain development in the children

[5] Physiology and Pathology of Mind, 1868.

[6] Mental Affections of Children (London: Churchill, 1898).

[7] Clouston: Neuroses of Development, London, 1891.

Classification of alleged causes —Ante natal hereditary brain disease or epilepsy, defects of ovum (syphilis ?), parental intemperance, age of mother, twin pregnancy, and intra uterine accidents (injury to mother, fright to mother, intra uterine diseases) Natal Causes acting at time of birth—premature birth lingering labour, and ophthalmia Post natal accidents—injury to brain, injury to organs of special sense and injury to body generally Diseases of brain, &c meningitis, hydrocephalus epilepsy, convulsions, chorea, and hæmorrhage (apoplexy) Maldevelopment in some definite area—e g , Broca's Disease of the spinal cord Friedreich's disease Diseases of special senses the eye, the ear the nose and pharynx, and the nose and adenoids Bacterial diseases whooping cough, measles, scarlet fever, typhoid fever diphtheria and fever Diseases of the lungs bronchitis, pleurisy, and pneumonia Diseases of the heart and of the kidneys General diseases rickets cretinism tubercle, rheumatism debility, want of appetite, &c , diseases of skin, eczema, &c This is a very long list, and it covers most of the diseases of children that are known to medicine I hope to show, however that most cases are not due to the operation of one cause alone with the exception of some of those due to hereditary brain disease and the obvious ones of accident or acute brain disease, such as hydrocephalus

Hereditary cases —After excluding some children who were not defective, and three or four in whose cases the cause was severe injury to the head in childhood, there remain for the purposes of my statistics 104 cases Of these, 28 or 26 9 per cent , had relatives who were either insane or epileptic These were grouped as follows epilepsy in family, eight , insanity 10 , imbeciles and idiots four , intemperate parents, three , and syphilis, one The last two items require explanation. The parental intemperance was very marked in these cases and it was almost certain that the parents were mentally of a very low type. Syphilis was placed here because it is so clearly an hereditary disease, and it is obvious that the age of the mother could exercise no effect on its transmission

Reasons for believing the causes probable —With regard to the second group of cases, where hereditary brain disease was not shown to exist, 76 or 73 1 per cent., of my cases were carefully examined, and I satisfied myself as far as possible that the causes given by the mothers as probable did correspond fairly well in the time of their occurrence with the time when mental deficiency was first noticed With regard to the 151 cases in the London board schools of which I have copied the notes I am not in a position to say as much , I have therefore not included these with my own cases, but have quoted them separately The close agreement in the percentages of the two series is remarkable and it strengthens the probability that the causes given are true and not merely apparent (No hereditary cases are included in the London series.)

AGE OF MOTHER.

Before directing attention to Table I on which I have tabulated the different causes, giving my own results in the first column and those from the London School Board in the second, I must explain that I leave for subsequent discussion what I have reason to consider the most important and frequent cause of all—namely, an advanced age of the mother at the birth of the child I mention it here because this cause must act on the ovum from its earliest age—that is if we leave out such questions as that of prolonged labour and lacteal supply, and therefore it should be grouped with the ante natal causes To consider the other causes *seriatim*

ANTE NATAL CAUSES

Syphilis —I only found undoubted hereditary syphilis in one case This is rather surprising, but it is borne out by the fact that only one of the London cases was assigned to this cause Hutchinson has noted the same fact among patients at Earlswood.[8]

Parental intemperance (No evidence of hereditary brain disease)—This is a very difficult subject on which to express an opinion I have already given reasons for including among hereditary cases the four cases from Leicester in which this cause was assigned If these reasons are admitted as valid there remains no case in which it is probable that this was the only cause of the child's condition Among the London cases two only have this as the sole assigned cause, though it appears in other cases in a

TABLE I —*Schedule of Causes*

—	Of my own 76 cases	Of 151 London cases
Ante natal causes—

[8] Clifford Allbutt : A System of Medicine, vol viii p. 235

different form, a not unusual combination being "intemperance of father, and his brutality to mother during pregnancy."

Twin birth.—In one instance in Leicester and in one in London this cause was assigned. Twins are frequently small and ill-nourished.

Injury to mother during pregnancy.—This is not stated in any of my cases. Four of the London cases are stated to have this cause. It is well known that abortion may be caused, or the placenta be partially or wholly detached, by injury causing death or serious malnutrition of the fœtus, and one can easily see the method by which this cause might obstruct brain development.

Fright to mother.—Of the Leicester cases two were assigned to this cause, as were also two of the London cases. In one of my cases the father was insane; in the other the child had also had an injury to the head at the age of three and a half years. This cause is so mixed up with the much debated subject of maternal impressions that I have great doubt of its validity, unless there has been actual physical injury at the same time.

NATAL CAUSES ARISING AT THE TIME OF BIRTH.

Premature birth.—This accounts for one case in Leicester and one in London. My case was evidently that of a very feeble child, for she did not walk or talk till the age of five years; she is deaf and speaks badly, but is not imbecile and profits by instruction. The arrest of cerebral development from this cause is easy to understand.

Lingering labour.—This was given as the cause of two London cases. Direct injury to the brain, rupture of vessels, and hæmorrhage, meningeal or otherwise, would probably be produced. Cyanosis, if recovered from, would probably not cause arrest of brain development. But stoppage of circulation might cause very serious lesions in nerve tissue.[9]

POST-NATAL CAUSES.

Injury to the brain.—Of this condition there were two cases among those from Leicester and two among the London cases. These require no remark, nor do those due to serious injury to the eyes or the body generally. Immersion in water, causing shock and subsequent pneumonia, is given in one of the London cases.

DISEASES OF THE BRAIN.

Inflammation of the brain.—This was alleged as to three London cases. It was impossible to inquire into them, but of course meningitis would naturally interfere with subsequent development.

Hydrocephalus.—I observed this in three cases. The heads were very large. The process appeared to have been arrested in all. It is impossible to say what the condition was due to. Probably to posterior basic meningitis. Tuberculous would not have been likely to be recovered from. There was one case from this cause among those from London.

Epilepsy.—There were nine Leicester cases and eight London cases. This cause is so well recognised that I need not say much about it. It must be remembered that the above small numbers only apply to the cases where heredity was not present or could not be proved, and that there were many other epileptics. The extent to which the mental capacity was affected by this disease varies much; some who only had an occasional fit were bright and learned well, while others who had frequent attacks were very dull.

Convulsions in infancy.—This was asserted to be the cause in six of my cases and in 10 of the London cases, or 7·9 and 6·9 per cent. respectively. The coincidence in the numbers is remarkable and shows, I think, that this is a real cause. I do not suppose that the causes of the convulsions are always identical. Some, no doubt, came on in the course of acute diseases or teething, while others might be true epilepsy now in abeyance and likely to appear again. The children in whom this cause only was alleged were, as a rule, not badly deficient mentally.

Chorea.—I have included this under brain disease as it is almost certain that the incidence of the toxin or bacillus, whichever it may prove to be, is mainly on the cerebral cortex, and this being so it is not surprising that its occurrence during the developmental period should cause mental defect, at all events for a time. Three of my cases and three of the London cases were due to it. An interesting question arises here as to whether some of the cases termed developmental and due to this cause among others may not really be true psychoses. I have recently seen a case of well-marked melancholia following an acute attack of chorea and another of chronic mania or dementia, and I shall later relate the case of a patient (Case 7) and give reasons for thinking that his deficiency may be due to dementia coming on at the age of five years after chorea.

Hæmorrhage into the brain or its membranes.—This is a rather frequent cause of mental deficiency. I found it in four of my cases and it was present in four of the London cases. Late contracture made cripples of these subjects. The mental defect was not severe in most of them. Whooping-cough was the cause of the hæmorrhage in one case. In two cases the children were the offspring of elderly mothers of the ages of 43 years and 41 years respectively at the time of the birth of the children. In all these cases there had been a distinct seizure or fit.

Defect of speech-area of the brain.—In Leicester there were two cases. I expect that these were really from the same cause as the last group, but I have no history of a distinct fit or seizure. The speech was very imperfect in both cases and there was impaired power of movement of the tongue in one case and of the lips in another. In neither was there anything like aphasia.

With regard to diseases of the spinal cord there was one case of Friedreich's disease and that was a London case.

The following are the returns of the diseases of the organs of special sense. From Leicester there were four eye cases and seven ear cases, and from London there were three of the former character and two of the latter, as well as two cases of disease of the pharynx and nose (adenoids). These are obvious causes of backwardness and perhaps of arrest of brain development in children. They do not call for much discussion. Many of the ear cases appear again under the headings of measles and scarlet fever. Blind and deaf cases are excluded, being all in special schools. The reason for the absence of cases with adenoids from the Leicester returns is special. The vice-chairman of the school board is Dr. F. W. Bennett, aural surgeon to the Leicester Infirmary, and he has taken great pains to have all such cases treated, with the best possible results. No doubt many more cases of backwardness from this cause existed before attention was so much directed to this condition.

GENERAL DISEASES.

This group corresponds to some extent to Dr. G. E. Shuttleworth's post-febrile group, but only partially. He, dealing with the more severe cases of idiocy and imbecility, has in his mind the cases where, as a result of the poison of one of the exanthemata, sclerosis with atrophy, or thickened and adherent membranes, following meningeal inflammations, were produced. I have no doubt that in some of my worst cases this may have occurred. In others, however, I consider that the brain has been affected along with, and in proportion to, the rest of the body, and that as a rule in this group of cases the cause assigned has been a secondary one, the primary or rather predisposing cause being the original weakness of the organism as a whole, due to pre-natal causes, especially to birth from an old and exhausted ovary.

Measles.—This disease appears more frequently than any other. There were 16 cases from Leicester and 21 from London. In several of the cases—one in four out of those from Leicester—there was some deafness due to middle-ear suppuration, but in others, though there was sometimes a discharge from the ear, there was no actual impairment of hearing. So common a disease as measles cannot be credited with being the sole cause, but along with the other exanthemata it is, I believe, a secondary cause in many instances. In several cases where there has been hereditary mental weakness imbecility appears to have followed an attack of measles.

Scarlet fever.—Of cases from Leicester there were six, and of London cases there were 12. Much the same remarks as those on measles apply to scarlet fever.

Of *fever* (indefined) there were two cases, both being from Leicester; while of *typhoid fever* there were three cases, all of which were from London.

Diphtheria.—From Leicester there were three cases, and from London there was one case. Apparently diphtheria is not a frequent cause. There has been much diphtheria in Leicester during the last few years.

Whooping-cough.—There were several cases of whooping-cough among those from Leicester, and they were generally in conjunction with measles or lung affection From London there were 11 cases. I have mentioned this complaint as leading to cerebral hæmorrhage in one case.

---

[9] Experiments on Spinal Cords by Ehrlich and Brieger (Pierre Marie: Diseases of the Spinal Cord, New Sydenham Society's Translations, 1895, p. 401).

Bronchitis.—The Leicester cases were six in number and those from London numbered 10. As far as I can ascertain, the bronchitis which is credited with producing mental defect is the rather dry, chronic, inherited form. The repeated attacks seem to interfere with cardiac action and circulation, as well as with proper blood aeration. It must not be forgotten, however, that such a complaint interferes very much with proper school attendance, and hence backwardness results, intensifying the effects of any cerebral maldevelopment.

There were two cases of *pneumonia* from Leicester and three from London.

Heart disease.—Leicester, four cases; London, six cases. In a few cases the condition was congenital; in others it was due to rheumatism.

Kidney disease.—There was one case of chronic nephritis after scarlet fever.

Rickets.—Leicester, one case; London, seven cases. I expected to find this a much more constant cause, and, indeed, in a few cases besides the one enumerated the skull was bossed, but I could not satisfy myself that there was any enlargement of the ends of the long bones or of the ribs. Also rickets is not a common disease in Leicester. The milk-supply is good and cheap and overcrowding in houses is uncommon.

Cretinism.—I do not know why none of the Leicester children and only one of those from London were cretins. There must be some that have escaped the school board net. The condition needs no remark, its effect on the brain being so well known.

Tubercle.—Leicester, four cases; London, eight cases. In some of its numerous forms tuberculous disease is responsible for a good many defective children. It must be remembered that many of the sufferers from tubercle are much too ill for any question of school attendance to arise. The cases which I have seen are mostly those of old bone disease.

Rheumatism.—When this is a cause it is usually through its secondary results of cardiac disease or chorea, which have been discussed.

Skin diseases.—There were two cases of eczema among the London cases. Probably this caused backwardness from the children being prevented from attending school; sometimes these cases are coincident with bronchitis.

Debility, want of appetite, &c.—Some of these cases have been included under other heads, but there appears to be a certain proportion of children who are extremely weak and who resemble the prematurely born. Some of these may possibly be tuberculous cases. Inability to eat breakfast is alleged about many of these.

TUBERCULOUS FAMILY HISTORY.

In addition to those diseases from which the children have suffered or are actually suffering there is the question of those cases noticed by Shuttleworth and others where there exists a history of tubercle in the family. In children of such families there is a want of resistance to the invasion of the tubercle bacillus and often to that of other micro-organisms, the germ of the exanthemata particularly. Such a hereditary condition as this has many points of similarity with that which I am about to describe and which I consider to be the most frequent predisposing condition of all—namely, the age of the mother at the birth of the child. Many of these causes will be found to coincide closely with those of idiocy given by Fletcher Beach and Shuttleworth,[10] and one observation of theirs is worth notice. They say: "Experience teaches that it is rarely scientific to assign one specific [illegible] When it is possible thoroughly to [illegible] contributing factors may be [illegible] the mother at the birth of the child is not noticed as a contributing factor.

Age of the mother.—As the forms relating to the family history of the defective children state the ages of the father and mother, the age of the latter at the birth of the child is known. I was struck by the fact that the age of the mother appeared to be excessive in many cases. I then tried to ascertain the average age of the child-bearing woman. This I found to be very diffic[illegible] returns do not give the ages of [illegible] children. Statistics exist of the ages of women at the time of delivery from many lying-in institutions in various parts of the world, and these show that a very great majority of the patients in those hospitals were under the age of 30 years at the time of delivery. There are, however, many objections to accepting these statistics as representing the state of matters with regard to the general population. Many of the births in lying-in hospitals are those of illegitimate children, and many others are cases in which women have contracted early and imprudent marriages, and the proportion of primiparæ to multiparæ is very high. The result is that in these institutions more children are born to women under 30 years of age than is the case throughout the entire population. I found, however, some facts reported by Dr. Matthews Duncan,[11] which were taken from a population resembling in many particulars those of Leicester and London, whence my statistics were derived. The ages of mothers at the time of delivery were stated in the Registrar's returns from the cities of Edinburgh and Glasgow between the years 1850 and 1860. I have taken these for comparison. I give shortly Dr. Duncan's remarks on these statistics:—(1) that the actual, not the relative, fertility of our female population as a whole at different ages increases from the commencement of the child-bearing period of life until the age of 30 years is reached and then declines to its extinction with the child-bearing faculty; (2) that the actual fertility is much greater before the climax, 30 years, is reached than after it is passed; and (3) that at least three-fifths of the population are recruited from women not exceeding 30 years of age. Dr. Duncan gives his figures distributed in quinquennial periods and I have tabulated my own cases in the same manner (Table II.). Taking all my cases where heredity has been excluded, instead of two-thirds of the children being born when their mothers were under the age of 30 years I find in the Leicester cases that the proportions have been very nearly reversed and that almost two-thirds were born to mothers over 30 years of age, and that 40 per cent. were born to mothers over 35 years of age instead of 20 per cent. as in the normal population, or exactly double. As justifying the exclusion of the hereditary cases these latter approach the normal very closely. The above has reference to the cases observed by myself. The London cases (151), where the facts were ascertained by independent observers, show the point almost as strongly. 40 per cent. are the children of mothers under the age of 30 years and 60 per cent those of mothers over that age. I believe that if inquiries as to heredity had been pushed further the proportions would have been the same as in the Leicester cases. One difference between the London statistics and those of Leicester is that there are more cases at the ages of from 30 to 34 years and fewer at those from 40 to 44 years. This, I think, may be due to the fact that the London women inhabiting Southwark and Clerkenwell, the districts in which the children lived, undoubtedly "age" more rapidly than do women in a comparatively healthy provincial town like Leicester. I do not believe that such facts with regard to 227 admittedly defective children can be accidental, and there are several further reasons for thinking that advanced age in the mother has an important bearing on the health of her offspring.

TABLE II.—*Showing the Relative Ages of Mothers of Normal and Backward Children.*

—	Under 25 years.	25–29 years.	30–34 years.	35–39 years	40–44 years.	Over 45 years.	Total.
Normal, Edinburgh and Glasgow, 16,301 cases							
Per cent.	24·92	30 89	23 61	14 76	5·15	0 61	100
Leicester, not hereditary—No. of cases...	14	14	18	13	14	3	76
Per cent.	18 4	18·4	23 7	17·1	18 4	4·0	100
Leicester, hereditary—No. of cases... ...	8	8	5	3	3	0	27
Per cent.	29 6	29 6	18 8	11·1	11·1	0	100
London, not hereditary—No. of cases...	26	40	47	24	11	3	151
Per cent.	17·2	26 4	31·1	16·0	7·3	2 0	100

Other facts bearing on the importance of the age of the mother.—This is not altogether a new observation. Not to go so far back as "Little Benjamin," the youngest of a family of 12, or to Aristotle who remarks that the young of very old parents are deficient in body and mind, we find a recognition of the fact in provincial speech: there is a dialect word used in Leicestershire and other counties to denote the smallest animal in a litter, and also the youngest weakly child of a family—*dilling*, often pronounced *dillon*.[12] Dr. A. M. Mitchell[13] quotes a series of 85 idiots and finds that while many of them were children of first pregnancies a much greater number were the children of the eighth, ninth, and subsequent pregnancies than would have been the case in the same number of children with normal brains; also that nearly 25 per cent. were born of mothers between the ages of 40 and 44 years, instead of 5·15 per cent. which would be normal. Shuttleworth[14] in discussing the Mongol or Kalmuck type of idiot remarks that almost half of the representatives of this type are the last born of a long family. Of course, this implies considerable age in the mother. My observations confirm these remarks, but though it is common to find that the defective child is the last of a large family the family is not always large nor is the child always the last one. Taking 18 children whose mothers were over 35 years of age at their birth at haphazard I find the size of the families to be eight, five, three, 10, 10, five, seven, five, four, seven, six, six, seven, 12, 15, 10, 11, and eight, six of the families being over 10 in number and 12 being less than that number. All these children except two were the youngest of their families. With regard to one or two general diseases the same cause has been referred to. Dr. A. Carroll and Dr. C. Morley Phillips,[15] treating of the causes of rickets, state that it is a recognised fact that a mother advanced in life, even though she has not had numerous previous confinements, is more apt to produce rickety children than is a younger woman. One point more should be considered. It may properly be argued, How do you explain the fact that there are so many cases in children of mothers under 25 years of age? In answer I must first state my general conclusion. It is that the above statistics appear to show that the most frequent causes of defective mental states in children who have no family history of hereditary brain disease are (1), as a predisposing cause, birth from a comparatively aged mother, and (2), as an exciting cause, some acute illness, most frequently one or more of the exanthemata, to which infections children of elderly mothers appear to be particularly liable.

---

[10] Clifford Allbutt: A System of Medicine, vol. viii.

[11] Fecundity, Fertility, and Sterility (Edinburgh, 1871).

Analysis of causes in children of younger mothers.—I am now in a position to discuss the reason why so many of these children are born of younger mothers. It is clear that certain post-natal causes are sufficient to cause mental deficiency in any child, healthy or otherwise, and my main contention is that the age of the mother produces in children the liability to be affected by causes which would not produce mental deficiency in healthier ones. (Tables III. and IV.) On the examination of the causes given as to children of mothers under 25 years of age we find that acute post-natal diseases are only alleged in five cases out of 13, while in those of mothers over 40 years of age we find acute post-natal diseases accounting for 12 cases out of 17. I think this very suggestive of the truth of my conclusion. In the London cases this is more marked, for acute exanthemata are a cause in the children of mothers under 25 years of age in only 15·14 per cent., while in those of mothers over the age of 35 years they are so in 45·1 per cent. Thus we find that when we are dealing with the children of younger mothers the causes of their mental defect are most frequently such as twin birth, premature birth, inflammation of the brain, accident to the mother, injury to the head, and cretinism—all causes which do not require a predisposing weakness of the child in order to produce mental deficiency; while in those of older mothers, these causes not being absent, we find in addition a large proportion in which the mental deficiency has been produced by such causes as acute post-natal diseases, which when attacking the stronger children of younger mothers have no such effects on the brain. It is to be regretted that the London School Board have recently omitted from their family history forms the ages of the fathers and mothers of the children, the importance of the age of the latter having evidently not been brought prominently before them. I now append a few typical cases.

Unknown	2	Bronchitis	3
Rickets	1	Scarlet fever	2
Whooping cough and cerebral hæmorrhage	1	Cataract	1

CASE 1. *Birth from a mother advanced in years; measles; abscess of the ears.*—The age of this child was nine years and nine months, and he was the youngest of eight children. His mother was aged 38 years at his birth, the father being of the same age. The boy's head was small and his expression was stupid. The palate was normal, the teeth were fair, the lobes of the ears were adherent, and the features were rather coarse. There was some corrugation of the forehead and the head was held rather on one side. The hands were normal in shape and the position when they were extended was normal. There was a good deal of twitching of the body when the boy was standing still. He had had measles severely in infancy, followed by abscess of the ears. He commenced to walk at the age of two years and to talk half a year later. In measurement he was two inches below the normal and he was two pounds under the normal weight. He could name objects well and he knew the day of the week. He could read a few short words, could write down badly words of three letters from dictation, could do a very simple addition sum but no subtraction, and was now (but only lately) fairly quick at manual work. His attention wandered very much and his memory was bad. He could not be trusted to perform an errand correctly. He was improving under special treatment, which he had been undergoing for a year. This is a typical case.

CASE 2. *The mother of advanced age; rickets; measles.*—In this case the child was of the age of seven and a half years and she was the sixth child, there being an interval of 11 years between the next oldest and herself. At the time of her birth her mother was 41 years of age and her father was of the same age Her head measured 20 inches and there were frontal and occipital bosses. The palate was normal, the teeth were bad, and the lobes of the ears were adherent, but the features were fairly good. She weighed four pounds less and measured two inches less than the normal. Her face twitched slightly, but the pose of the head was normal. The hands were normal in shape but the fingers were over-extended. The body was normal and she was cleanly in her habits. She had suffered severely from rickets, she walked badly, and she had had bronchitis and measles. She talked at one and a half years and walked at three years of age. Her powers of observation were weak, but she could name objects, and she knew the day of the week, could read words of three and four letters, and could write words of three letters from dictation. She had no idea of numbers. She had improved under special training for one year, but still she had no idea of numbers. This was not such a severe case as the previous one.

CASE 3. *Delicate; bad eyesight.*—This child was eight years of age and was the twelfth or thirteenth of a family of 16 children. When she was born her mother was 35 years of age and her father was the of same age Her head measured 17 inches Her expression was vacant the palate had rather a high arch but was not narrow, the teeth were fair, the ears were badly shaped and rather pointed, and the features were coarse She was five inches in measurement and 19 pounds in weight below the normal standard She had small thin hands which presented a drooping position when extended In her habits she was cleanly but she was always cold and had never been well Her eyesight was bad and she was slow in her movements She walked and talked at the age of two years She imitated movements slowly, read fairly, wrote very badly, and could only calculate up to four, but she could do manual work. Her health was very defective and her sight had also prevented the development of intelligence

[12] Skeat: English Dialect Dictionary.

[13] Edinburgh Medical Journal, January, 1886.

[14] Mentally Deficient Children, second edition.

[15] Brit. Med. Jour., Sept. 21st, 1895.

CASE 4 *The youngest of 16 children, bronchitis* —This child, who was seven and a half years of age was one of 16 children most of whom had died in infancy, several from bronchitis The mother was 41 years of age at the time of the birth of this child and the father was one year older The head was normal, measuring 19½ inches The expression was bright, the palate was normal, the teeth were good the ears were normal, and the features were good In height she was two inches above and in weight two pounds below the normal The head was held on one side The hands were normal in shape and pose There was some twitching of the body Her habits were cleanly She had suffered much from bronchitis The father had chronic bronchitis and he had had dry eczema She looked a bright girl but was not too strong in the moral sense She could only read write, and count in the most rudimentary way but she could do manual work fairly well This child would have quite escaped all notice on Dr Warner's plan of examination Not any of his developmental or nervous signs were present, yet she was very defective

CASE 5 *The mother of advanced age, bronchitis* —The age of this child was seven years At the birth of the child the mother was 42 years of age and the father was of the same age The head measured 19½ inches, the expression was bright, the palate was normal, and the teeth were fair but the ears were not of good shape In height the child was four inches and in weight nine pounds less than normal—a very small, delicate-looking child Severe attacks of bronchitis had been experienced The child's habits were cleanly Objects were named with difficulty and the day of the week could not be told The child could only read words of two letters, could hardly write anything, and counting was very deficient, but the moral sense was good

CASE 6 *The mother advanced in years, chorea* —This child, the ninth of 11 children was of the age of seven and a half years The two children who were younger than himself had died from tubercle of the abdomen (?) The mother was 37 years of age at the birth of the child and the father was 39 years of age The boy's expression was dull, the palate had rather a high arch but was not narrow, the teeth were fair, the ears were coarse and they stood out, and the nose was broad The height and weight of the child were normal The head was held on one side, the hands were badly formed, and there was weakness in the pose as well as restlessness He had had chorea three times The memory was fair and he could read short words, count a little, and do manual work He was a very nervous child, but his condition was better than was that of the other children whose cases I have reported and he ought to do well

The last case is one to which I have already referred as being probably psychosis and not entirely a case of arrest of cerebral development

CASE 7 This boy, when I first saw him six months ago, was 11½ years of age His head which was narrow, measured 20½ inches At his birth his mother was 45 years of age and his father's age was 48 years He had a sullen and dull expression The palate was normal, the teeth were good, the ears were normal but the features were rather coarse In height he was one and a half inches and in weight five pounds under the normal He squinted slightly The head was fixed and the hands were weak in pose He had had measles and scarlet fever at the age of four years followed by left hemichorea which had existed ever since more or less till recently Two years previously he was pronounced to be an idiot by the medical attendant of the family I certified him to be an imbecile He could not name objects, could not read any letters or write, would not answer a simple question and was reported to lie, to steal and to be uncleanly in his habits and also to wander about the streets and to lose himself Now he certainly is not an imbecile; he can be entrusted to carry out an errand, can name objects well can answer questions, does not wander about or steal and is cleanly in his habits Such improvement, morally as well as mentally, indicates to me that this was a case of dementia following chorea I have lately met with two similar cases—one of typical melancholia and the other of chronic mania or dementia—following the same primary disease In this case I have no doubt the weakness of constitution derived from the excessive age of the mother predisposed to the mental affection

To sum up, the most careful observers divide the causes of mental weakness into pre natal natal, and post-natal With regard to the two latter groups my cases fall in with those given by other observers notably Beach and Shuttleworth[16] They, however, are evidently much impressed with the fact that in most cases there is a congenital weakness of constitution which, when acted upon by post-natal causes, induces the maldevelopment of the brain Even in their more serious cases of idiocy and imbecility, however, they are only able to point to somewhere about 40 per cent in which there was a family history which would account for such defect I claim that the excessive age of the mother will account for such congenital, though not hereditary, influence in from 60 to 70 per cent of the remainder

Dr Warner has so kindly placed all the information which he possesses at my disposal that I feel very reluctant to call his conclusions in question. There are, however, one or two points in which my results differ from his and which I should like to indicate In the first place, as I have already stated, all the observations on the 100,000 children in the report[17] are based on the assumption that it was impossible to ascertain facts as to family history and that it was also impossible to make physical examinations of the children Under the new Act these are now both possible Next, the statement is made "It is in the co relation of abnormalities in the proportion of parts of the body, with abnormal nerve signs, low nutrition and mental dulness that we find a criterion of the really defective status connected with the abnormality and the value of such signs "[18] I am not sure that I understand this but I take it to mean that there is some defect in the brain in these cases that we cannot detect by taking the ordinary methods of ascertaining the child's mental faculties To this I cannot assent It appears to me that we can ascertain the state of development of a child's brain at least as well by asking such child to name objects or by testing the memory &c, as by looking at the cranium, palate, hands, &c, and co relating any malformation of these with corrugated superciliary muscles, open mouth, or twitching fingers I do not wish to say that the results of the examination of so many children are useless, no such accumulation of facts can fail to be useful at some time or another to someone but when Dr Warner[19] states that ' by the analysis and study of such observations we are enabled to determine the causation and the treatment of mental diseases" I think he goes beyond his facts What are the signs on which he relies?[20] The first is that of the defects in development of the body and its parts in size form, or proportion "such signs appear to indicate inborn and fixed constitutional tendencies ' This is the doctrine of stigmata and I take leave to say that it is wholly unproven No one will deny that a child with a very imperfect brain may happen at the same time to have an imperfectly developed body and may even be *likely* to have this but I do deny that bodily imperfections are as a rule, an index of brain development Phrenology we have discarded We have Socrates to quote, or rather Plato, against the theory that the face is an index of the mind, and I will now state a few facts with regard to two of the supposed defects

The cranium —The measurement of the cranium is proverbially difficult The direction given by the committee[21] is that heads less than 19 inches in circumference after three years of age are to be considered small I venture to think that a careful inspection of any hatter's stock would show that hard and fast lines of this sort are of little value

The ear —This, if large and outstanding, or with imperfect helix, is supposed to indicate defect This is a favourite

[illegible] A System of Medicine, vol viii [illegible] Physical

[18] [illegible] p [illegible]

[19] Clifford Allbutt: A System of Medicine, vol viii, p 193

[20] Ibid., p 199 [21] Ibid, p 20

subject with a class of writers who resemble those on palmistry, and a work has been written entirely on this subject.[22] The reviewer of this work in *Nature*, Dr. Keith,[23] relates how he himself had examined 40,000 ears of dwellers on both sides of the German Ocean in an endeavour to discover if any traces of affinity of race could be found by this means. His results were negative, but he affirms that he convinced himself that every form of ear may be found in persons of every grade of life and standard of intelligence, and that what has been described with confidence as the "criminal ear" is the normal form for inhabitants of these islands.

The palate.—The shape of the palate has great prominence given to it, and I have consequently made a good many observations with regard to it. The committee state that it has a high pathological co-relation. I found in 80 cases of mental defect that the palate had a high arch in 34, it was doubtfully high in eight, and was normal in 38. This does not seem a high percentage, and in the seven cases which I report fully, which were selected on quite other grounds and in which I had not specially noticed the condition of the palate, I found five to be normal, one doubtful, and one high. A diagnostic sign which misses five out of seven is not worth much.

I thought it worth while, having the opportunity, to ascertain if this sign and that of nervous pose of the hands were absent from children admittedly not defective, at all events as to their capacity for learning, and I therefore examined 500 children in the fifth, sixth, and seventh standards in the Leicester schools. I found in some of the higher standards examples of the most deformed palates, high-arch, V-shaped, and asymmetrical; and the totals worked out: examined 500, with high-arched palate 135, with hands of weak balance 126. Thus showing that half as many in proportion of the brightest children had high palates as the defective ones.

Nerve-signs, so-called, form the second of Dr. Warner's signs. These undoubtedly in many cases are an indication of irregular discharge of muscular impulses, and as such deserve attention; but many of these, especially the twitching of the face and hands, are really chorea and depend on a definite pathological condition of the cortex, while others are secondary to injuries of the brain or cord (athetosis in birth palsies).

The third sign on which Dr. Warner relies is that of low nutrition. This has in some cases a connexion with the mental enfeeblement. Dr. Warner says:[24] "It is among the children with defects in bodily development that we find the largest proportion of the pale, thin, delicate children whose tissue delicacy is connected in causation with the defective symmetry of features and parts of body." I have already explained that I consider most of the cases of extreme delicacy to arise in the children of old mothers who have been attacked by acute diseases, and this condition is not hereditary in any other sense than that it is partly congenital. I must state here, as I have done previously, that Dr. Warner himself allows that there is a small class of dull children who do *not* show defect, and that a considerable portion of children showing defects are not mentally dull. I therefore think that while undoubtedly those children with arrested brain development have more frequently than healthy ones signs of abnormal development in other organs, yet these signs are not so much more frequent in them as to give us much help in the diagnosis of the condition, which, moreover, can be readily ascertained by other methods.

CONCLUSIONS.

If the theory that a very large percentage of those cases can be accounted for by pathological or accidental causes acting on congenital weakness not of an hereditary character is true, does it afford any ground for believing that such conditions are likely either to increase or to decrease? The hereditary cases will no doubt for a long time continue about the same. State regulation of marriage is almost the only measure that could control them, and that appears as yet to be far distant. The law of reversion to type and intermarriage with healthy stock will no doubt prevent their increasing to any great extent, even if they do not diminish. With regard to the children of elderly women I think that some good may be done if it is freely recognised that women who bear more than a moderate number of children run the risk of bringing weakly ones into the world, that the same remark applies to women much over 30 years of age, and that if such children are born they require additional care, and in particular protection from the germs of infectious diseases.

Leicester.

THE TREATMENT OF GLAUCOMA BY EXCISION OF THE SUPERIOR CERVICAL GANGLION OF THE SYMPATHETIC.[1]

BY A. L. WHITEHEAD, M.B., B.S. LOND., &c.,
OPHTHALMIC AND AURAL SURGEON TO THE GENERAL INFIRMARY AT LEEDS.

AT the present time, when the advisability of removing the superior cervical ganglion of the sympathetic for glaucoma is under consideration, the following case is of great interest.

A man, aged 23 years, was admitted into the Leeds General Infirmary under my care on Oct. 28th, 1899, for injury to the left eye sustained by the bursting of a soda water bottle. There was a small lacerated wound at the corneo-scleral junction, into which the base of the iris was prolapsed. The patient was warned of the possibility of sympathetic trouble, but went home as soon as the wound healed and was not seen again until March 31st, 1900. He then returned with intense irido-cyclitis in the left eye and in the right eye marked sympathetic iritis, which had set in three weeks previously to his second admission. The left eye was excised, the sight being quite lost, and under atropine, leeches to the temple, &c., the right eye rapidly improved, the pupil dilated, and the iritis subsided. He went out on May 12th, when the eye was quiet and vision was $\frac{6}{12}$. On August 11th the man returned, vision having rapidly failed within the previous three weeks. There was then considerable ciliary congestion, the anterior chamber was shallow, the pupil was fixed, and the iris was swollen and acutely inflamed. Tension was + 3 and the vision was reduced to ability to count fingers at six inches. Paracentesis of the anterior chamber was performed without giving relief, and three days later iridectomy was attempted but could not be satisfactorily performed, the iris being found to be firmly adherent to the lens throughout its entire breadth. Tension remaining + 3 paracentesis was performed on the 29th and on Sept. 20th, and iridectomy was again attempted on the 29th. On Oct. 3rd sclerotomy was performed; tension, however, rose again to + 3 on the following day. On the 7th it was decided to remove the superior cervical ganglion of the sympathetic, which operation Mr. B. G. A. Moynihan at my request performed on the same day. The ganglion was reached through an incision behind the posterior border of the sterno-mastoid, carefully separated from the surrounding parts, and excised.

The immediate effect of the operation was striking, the tension of the eyeball falling rapidly to + ½, although there was no contraction of the pupil, the iris being fixed as described above. The following day (the 8th) tension rose to + 2, but two days later it was + ½ and vision had improved to ability to count fingers at 14 inches. There were slight fluctuations in the tension from day to day, but the improvement in vision was maintained until he left the hospital on the 30th. I saw him again on Jan. 5th, 1901, and found the tension + 1 and vision = ability to count fingers at 18 inches. No treatment, local or constitutional, was carried on subsequently to the operation, so that the reduction of tension and improvement in vision must be attributed entirely to the removal of the ganglion.

The effects of the operation are immediate and secondary. The immediate effects are relief of pain in the eye, contraction of the pupil when not fixed by adhesions, congestion, and lacrymation of the eye, reduction of tension, and unilateral sweating of the head; the secondary effects are progressive reduction of tension, sometimes preceded by a temporary rise, gradual improvement in vision, slight ptosis, and some sinking of the eyeball into the orbit. The lacrymation, congestion, and sweating usually disappear within 48 hours.

[22] The Human Ear: Its Identification and Physiognomy.

[23] Nature, vol. lxiii., p. 392.

[24] Ibid., p. 199.

[1] A paper read before the Leeds and West Riding Medico-Chirurgical Society on March 15th, 1901.

The exact manner in which this operation gives relief in glaucoma is a matter of some doubt. Jonnesco[2] of Bucharest thinks that glaucoma is caused by a central lesion and that removal of the ganglion destroys the communication between this centre and the eye The vaso constrictor fibres are destroyed, blood-pressure is lowered, and extravasation is reduced. The excito-secretory fibres to the uveal tract are destroyed and the secretion of the aqueous is limited The iris dilating fibres are destroyed, the pupil contracts, and the filtration angle is opened up At the same time the fibres supplying the non-striped muscle in Tenon's capsule are cut off, so that the pressure on the efferent veins is removed

From a consideration of this case it is clear that the contraction of the pupil, drawing the iris away from and so opening up the filtration angle following the removal of the ganglion, is a minor factor in the reduction of tension It is obvious that the control of the sympathetic over the circulation and nutrition of the uveal tract is of much greater importance We know that in many cases of serous cyclitis the filtration angle is free and unobstructed, and the rise of tension often seen is due to changes in the constitution of the intra-ocular fluid It seems highly probable, therefore, from the *rapidity with which the tension fell after the completion* of the operation in the present case, although the pupil could not contract, that the good results which were seen after the performance of this operation were due, not so much to any change in the filtration angle brought about by contraction of the pupil, but rather to the abolition of the control of the sympathetic over the vascular apparatus and secreting epithelium of the uveal tract, whereby the character and amount of the intra-ocular fluid were materially altered.

Sympathectomy for glaucoma was first performed by Jonnesco in 1897 and since then has been carried out by many surgeons abroad and in England Abadie,[3] Panas,[4] Ball[5] (St Louis), Burghard,[6] Work Dodd,[7] and others have recorded cases In Jonnesco's cases, which were chronic or subacute with only one acute case, very encouraging results were obtained There was marked and permanent improvement in vision in all the chronic cases except those in which optic atrophy had set in, but there was no improvement in the acute case In all cases the tension was immediately lowered and remained so and there was marked permanent contraction of the pupil with loss of pain in the eye In the cases reported by Panas and Burghard the results of the operation were unsatisfactory and in Work Dodd's case disappointing Ball's two cases were relieved, tension being reduced and vision improved, but there is no evidence that iridectomy would not have been equally effective In Burghard's case intense pain at the side of the head and neck followed the operation This unpleasant complication has been recorded by other operators From a general consideration of the recorded cases, with the present large percentage of comparative and complete failures, it is probable that the severity of the operation as compared with iridectomy will prevent its performance in any but selected cases, particularly those in which iridectomy and sclerotomy have failed

In glaucoma simplex the results have been more uniformly satisfactory than in inflammatory cases, but in the latter when iridectomy has failed sympathectomy holds out some hope of relief In, however most cases of glaucoma arising from obstruction in the filtration angle, especially acute cases, iridectomy will remain the operation of choice and will be found to give equally satisfactory, or even better, results than follow removal of the superior cervical ganglion of the sympathetic

BRISTOL MEDICAL CHARITIES —The late Mr. J E. Exley bequeathed £1000 each to the Bristol Royal Infirmary, the Bristol Children's Hospital, and the Queen Victoria Convalescent Home, Bristol also £500 to the Trowbridge Cottage Hospital The residue of the property is left to his widow during her life in trust for the Bristol Royal Infirmary, which will eventually become entitled to about £15,000.

ON THE PATHOLOGICAL CHANGES IN A CASE OF PROGRESSIVE MUSCULAR ATROPHY.

BY R. T. WILLIAMSON, M D, F R C P LOND,
PHYSICIAN TO THE ANCOATS HOSPITAL, MANCHESTER, AND ASSISTANT LECTURER ON MEDICINE, OWENS COLLEGE

DURING recent years many distinct clinical varieties of chronic muscular atrophy have been separated from progressive muscular atrophy Hence cases to which the term "progressive muscular atrophy" can now be applied are rarely met with, and several writers have grouped together progressive muscular atrophy and amyotrophic lateral sclerosis as the same disease In cases regarded as progressive muscular atrophy during life the lateral or crossed pyramidal tracts of the spinal cord have very often been found sclerosed more or less on pathological examination, even though there has been no spastic condition of the legs, and this is one reason for grouping together amyotrophic lateral sclerosis and progressive muscular atrophy as one pathological affection or one disease A few rare cases are on record, however, in which during life the symptoms were those of progressive muscular atrophy (of the Aran-Duchenne type), and on pathological examination of the spinal cord the lateral or crossed pyramidal tracts were found to be normal Such cases have been recorded by Dr C E Beevor, Professor Strümpell and MM A Dutil and J B Charcot and others (In several cases there has been a slight degeneration of nerve fibres in the anterior ground bundle close to the anterior horns though the crossed or lateral pyramidal tracts were normal, in other cases all parts of the anterior and lateral white matter were normal) To the few cases hitherto recorded the following pathological report may be added, it appears to be worthy of publication owing to the rarity of such records

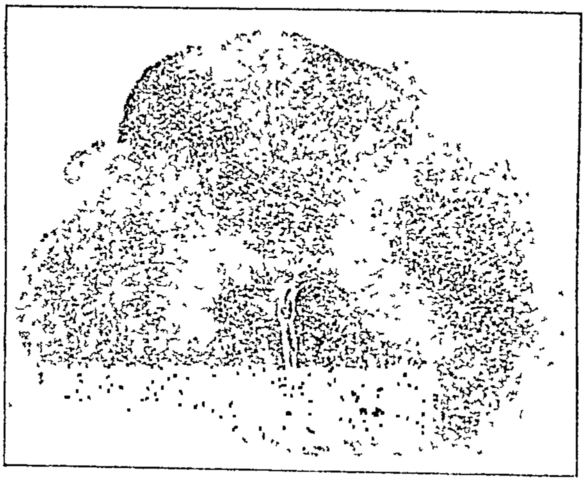
The spinal cord of this case was kindly given to me by the late Dr Leech of Manchester, who, had his life been spared would probably have written the clinical portion of this article My report will be devoted, therefore, to the microscopical examination, and to this I have added a brief clinical note of the case which I had the opportunity of examining from time to time, for many years, when the patient consulted Dr Leech at the Manchester Royal Infirmary

I first saw the patient, a man of middle age, in 1879 At that time both arms were paralysed, and the disease had commenced a few years previously I last examined the man, along with Dr Leech, in 1898 The patient died about 12 months later The clinical features of the case were those of progressive muscular atrophy (of the *Aran-Duchenne type*) as described in the older text books There was slowly progressing muscular atrophy, with paralysis, affecting the small muscles of the hands, the forearm and the upper arm muscles, and finally the muscles of the neck The arms for 20 years hung quite helpless by the side and the head was bent forwards There was no affection of sensation, and the legs, bladder, and rectum were unaffected up to the time of the last examination On many occasions I examined the condition of the legs with the object of ascertaining whether there was any evidence of spastic paralysis, but I was never able to detect any When I last examined the patient in 1898, 12 months before his death and more than 20 years after the onset of the disease, the condition was briefly as follows Both arms were markedly atrophied and completely paralysed and hung quite helpless by the sides Every muscle of the hands and arms appeared to have atrophied completely The head was bent forwards owing to the paralysis of the muscles of the neck. There were no symptoms of bulbar paralysis The bladder and the rectum were unaffected The patient was able to walk quite well There were no indications of a spastic gait There was no paresis of the muscles of the leg nor any rigidity to passive movements The knee jerks were present and there was no ankle-clonus Sensation was not affected Clinically, therefore, there were no symptoms to indicate any affection of the lateral pyramidal tracts of the spinal cord at the end of 20 years I did not see the man during the last few months of his life and do not know the exact cause of his death Dr W H Pomfret, formerly surgical registrar at the Manchester Royal Infirmary, having heard of the patient's death, succeeded in getting permission to make a limited post-mortem examination. He removed the spinal cord, the musculo-spiral nerve, and a piece of the adjacent muscular tissue of the forearm. To Dr. Pomfret, therefore, I am directly indebted for the specimens which he kindly forwarded to me with the permission of Dr. Leech The specimens were hardened in Müller's fluid, embedded in celloidin, and the sections were stained according to Weigert's and Marchi's methods, and also with aniline blue-black and logwood. The nerve roots were stained according to Heller's pyrogallic and osmic acid method.

Microscopical Examination.

In the lower and middle cervical regions, on transverse section, whether stained with aniline blue-black, logwood, or according to Weigert's or Marchi's methods, the crossed or lateral pyramidal tracts of the white matter appeared to be quite normal (Fig. 1). Also the direct pyramidal tracts and all the white matter of the anterior and lateral columns of the cord appeared to be normal with the exception of a very slight excess of neuroglia connective tissue in the region of the direct cerebellar tracts. The white matter in the antero-lateral columns close to the anterior horns appeared quite normal. In the anterior white commissure, in the sections stained according to Weigert's method, the nerve fibres were seen very distinctly. In the posterior median columns there was a very slight excess of neuroglia connective tissue (seen both in sections stained according to Weigert's method and in those stained with aniline blue-black), but the posterior external columns were normal. The anterior horns of grey matter were a little smaller than they are in sections of a normal cord at this region. The ganglionic nerve cells of both anterior horns had disappeared. After examining a number of sections of this region I was only able to find one atrophied nerve cell in the median region of one anterior horn. On examining sections stained according to Weigert's method the disappearance of nerve fibres in the anterior horns of the grey matter was very evident. The fine delicate nerve fibres (seen so clearly in the normal anterior horns in sections stained according to this method) were greatly diminished in number (Fig. 3). The fine nerve fibres of the posterior horns appeared to be normal. The nerve fibres from the posterior roots which enter the median side of the posterior horns were quite normal and were seen passing forwards to the intermediate grey matter, whilst the fine fibres in the surrounding median grey matter were diminished in number. In sections stained with logwood and eosin the nuclei of the neuroglia in the anterior horns were seen to be increased in number. The anterior nerve roots, even to the naked eye, appeared to be markedly atrophied; they were much smaller than the posterior roots and much less firm to the touch. On microscopical examination the posterior roots were normal, but the anterior nerve roots were seen to consist chiefly of fibrous tissue and empty nerve sheaths, with here and there a very few normal nerve fibres.

Fig. 1.



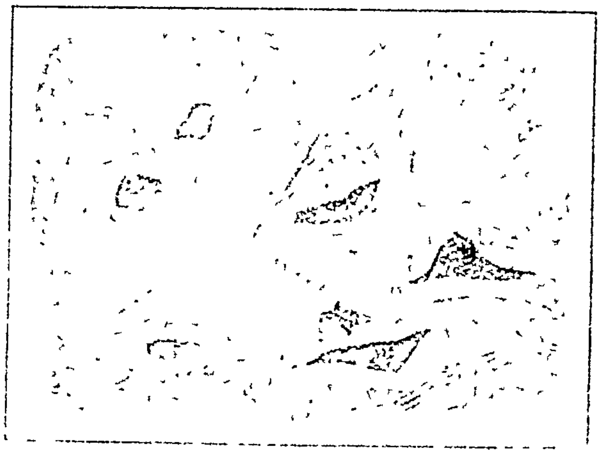
Transverse section of spinal cord, lower cervical region; progressive muscular atrophy; Weigert's stain; crossed pyramidal tracts normal. (Micro-photograph.)

The few remaining normal nerve fibres in the anterior roots were widely separated by fibrous tissue (as was well seen in specimens stained according to Heller's method). There was marked "hyaline" thickening of the walls of the small bloodvessels in the anterior median fissure and in the anterior horns of grey matter.

In the upper cervical region the condition was much the same. Most of the nerve cells in the anterior horns of grey matter had disappeared or atrophied markedly. The crossed or lateral pyramidal tracts and other parts of the white matter were normal, with the exception of a very slight excess of neuroglia connective tissue in the posterior half of the posterior median columns. Sections of the dorsal region (upper and lower) presented normal appearances. The lateral or crossed pyramidal tracts, the posterior columns, and other parts of the white matter appeared to be normal both in sections stained according to Weigert's and Marchi's methods, as well as in those stained with aniline blue-black. Some of the nerve cells in the anterior horns and in Clarke's columns were pigmented, but otherwise the cells and fibres in both of these regions appeared to be normal. The anterior nerve roots, to the naked eye and on microscopical examination, were normal in the dorsal region.

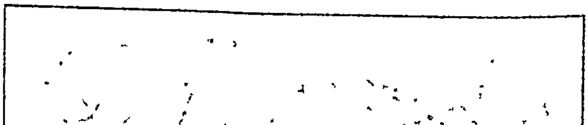
In transverse sections of the musculo-spiral nerve most of the bundles of nerve fibres appeared to be normal; in a few bundles there was a little increase in the connective tissue between the separate nerve fibres. The atrophied muscular tissue from the back of the forearm presented a very slight

Fig. 2.



Normal anterior horn of grey matter, cervical region; Weigert's stain; showing nerve cells and numerous fine nerve fibres.

Fig. 3.



Grey matter of anterior horn, lower cervical region; progressive muscular atrophy; Weigert's stain; nerve cells absent; fine nerve fibres very scanty.

resemblance to normal muscle to the naked eye, but it was very soft and flabby. On microscopical examination, however, the changes were most marked. Not a single normal striated muscle fibre could be detected. In place of the muscular tissue were collapsed muscle sheaths containing numerous elongated or round muscle nuclei which stained with logwood. Between these bundles of collapsed, well nucleated, muscle sheaths there was loose connective tissue, with a few clusters of large fat cells here and there. No evidence of hyaline or fatty degeneration of muscle fibres could now be detected.

The microscopical examination here recorded is of interest, because the case is one of the few which furnish clear pathological evidence that the crossed or lateral pyramidal tracts may appear normal in cases which have presented the symptoms of progressive muscular atrophy (of the Aran-Duchenne type). The crossed or lateral pyramidal tracts, from the highest cervical to the lowest dorsal region, presented no evidence of degeneration on microscopical examination, even in sections stained according to Marchi's and Weigert's methods. Also during life, up to the time of the last examination (more than 20 years after the onset of the disease) there were no symptoms of disease of the crossed pyramidal tracts.

Progressive muscular atrophy is closely allied to amyotrophic lateral sclerosis, and probably the pathological processes are in many respects similar; also there are transitional forms—cases corresponding clinically to progressive muscular atrophy, but pathologically to amyotrophic lateral sclerosis more or less. There is, however, a small group of cases which, both clinically and pathologically, differ from amyotrophic lateral sclerosis—cases such as that described in this article, and those previously recorded, to which I have referred. For these cases it appears advisable, at present, to retain the old name of "progressive muscular atrophy."

TETANY.

BY FRED. TRESILIAN, M.D., M.R.C.P. EDIN.

TETANY, which is not an uncommon disease in children, is somewhat rare in adults, and therefore a few cases which have occurred in my practice of which I kept notes may be worthy of record.

In adults tetany is largely confined to women, being frequently associated with either pregnancy or lactation; it was primarily recognised by Trousseau in this connexion. It is only very occasionally—perhaps never—that it appears as a primary condition, being generally caused by some other disease of which it would seem to be a result. It has no special pathology of its own—at least, none has as yet been discovered—and it is apparently due to a reflex irritation of the excitable portion of the cortex—i.e., the motor areas, either alone or perhaps with the groups of cells in the anterior cornua of the cord. Clinically it is connected closely with epilepsy and chorea. Its association in adults with dilatation of the stomach is now established, and two of the cases which I have recorded below are an evidence of this point. The cases of this kind are mostly confined to the female sex. It may be assumed in these cases with gastric dilatation that it must be due to absorption from the stomach of toxins due to fermentation of food acting on the cells in the motor regions of the brain. In one of my cases this was manifest and the result was fatal. A similar explanation may be given of its occurrence in infants in association with diarrhœa and gastro-enteritis, in which conditions fermentation is nearly always present and toxins are in abundance, and even in rickets similar causes may be at work and may account not only for tetany but other nervous lesions, such as eclampsia and laryngismus, which are so frequent. Even those cases occurring in connexion with pregnancy or lactation, as well as those recorded by Weiss and Wölfer after excision of the thyroid gland, may possibly be explained by the same hypothesis—of some toxin present in the blood which affects the cortical grey matter. I have but six cases to record and four of these are in children.

CASE 1.—The patient was a male infant, aged seven months. He cut his first teeth at five months and was a healthy child. He had sudden attacks of convulsions—both tonic and clonic spasm—which continued for three days, when acute pneumonia appeared in the right lung. The convulsions continued intermittently for a week until the pneumonia began to clear up, when they ceased. This was followed by an attack of diarrhœa and sickness, which got better in a few days and left as a result constipation with large hard masses of fæces. The child was very much reduced by his illness and the tetany occurred while he was in this condition. There was marked tonic carpo-pedal spasm which was continuous even in sleep. The position of the hands was characteristic and the toes were flexed into the soles. There was considerable œdema of the face and of the backs of the hands and feet which were solid and non-pitting. There were jerky twitchings of the hands and arms. The condition lasted for some weeks and then got well. There was no evidence of rickets in this child. The treatment adopted was the administration of syrup of chloral and emulsion of cod liver oil. Carpo-pedal spasms are a rudimentary form of tetany, but are much more common than real typical tetany.

CASE 2.—The patient was a male infant, aged 15 months. There were no signs of rickets. He had been, and was at the time of treatment, a fine, healthy child. His first teeth had come when he was seven months old and he had got teeth rapidly within the following two months. He had been suckled and had lately had food as well. There was no history of diarrhœa or convulsions and no assignable cause for the present attack. There were contraction, tonic spasm, and œdema of both hands and feet. He had a cough with a crowing sound—"like a fowl crowing," his mother described it—evidently associated here with laryngismus which is essentially a rickety neurosis, still I could find no outward and visible signs of rickets.

CASE 3.—The patient was a female infant, aged three years, a stunted, rickety child, of about the size of a baby of eighteen months of age. I think this was the most marked case of rickets that I have ever seen. The child had never made any attempt to walk, she did not get a tooth until long after she was 12 months old, she had many attacks of both bronchitis and convulsions, and she had distorted joints and spine, &c. There was so much œdema of the face and hands that I examined the urine for albumin. The position of the hands and feet was just as in the other cases.

CASE 4.—This was an exactly similar case to the last. The patient was a stunted, rickety female child, aged two years, whom I had attended for both convulsions and bronchitis.

CASE 5.—The patient was a married woman, aged 41 years. The present was her third attack. The first had occurred 11 years before soon after her confinement, when she had got up and was suckling her infant. She had loss of feeling in the feet and pain and spasm in the hands and also, she said, loss of sight which lasted three days. She said that she felt at the time as if her face was greatly swollen but that it was not swollen and that this condition lasted then for six or seven weeks. She asserted also that she lost her speech for part of a day. Seven years ago she had another attack in just the same way after a confinement and while suckling her baby. This attack was not quite so severe as the previous one, but still it lasted for four or five weeks. She had recently had influenza. She had just nursed her daughter through a long attack of peritonitis, and she had recently moved from one house to another and had not got straight when the influenza occurred. I mention this to show that the patient had a good deal of both anxiety and worry. The position of the hands was characteristic and the spasm of the interossei so much that she could not separate the fingers, and my efforts to help her to do so evidently caused her great pain. There was a good deal of pain in the hands and arms. The feet were unaffected; sensation in both hands and feet was normal. On examining the abdomen I found marked dilatation of the stomach, reaching down to below the umbilicus. There were dulness at the lower level, a tympanitic note above, and a distinct splashing sound on succussion. Peristaltic action was evident and retention of food with periodical vomiting of large quantities of sour fluid. The condition disappeared in about a week. This case is interesting from the fact, if true, that she had temporary aphasia and loss of sight. It shows that the toxin which causes the tetanic spasm to appear is capable of attacking other regions than the motor part of the cerebral cortex, and that the motor area is not exclusively selective.

Case 6.—The patient was a woman, aged 53 years. I first saw her in October, 1900, when she had suffered from gastric symptoms for eight months and pain and vomiting with loss of flesh. On examination I found extreme dilatation of the stomach reaching downwards to the hypogastrium, with marked peristaltic action from left to right on stimulating the stomach to contract. There was a hard, square, nodular tumour over the pylorus which was tender on pressure. She vomited enormous quantities of thick fluid daily or on alternate days, with ease to her pain. There was advanced malignant disease of the pylorus. She held her own until Dec. 20th, when I was called urgently to see her and found her comatose. The condition was peculiarly interesting. The face, hands, arms, and body in general were of a dark red colour with a bluish tinge. The hands were in the position characteristic of tetany. There was slight flexion of the wrists, but the fingers were extended at all joints and were opposed to each other. The feet were similarly affected, each foot being extended with the toes flexed into the soles. The pupils did not react to light and the conjunctival reflex was absent. She had had two convulsive attacks previously to my seeing her, and she had one in my presence in which she became livid and after which the colour became dark red as before. The convulsions were chiefly facial, with twitchings of the arms. There was incontinence of urine. During and after the eclampsia there was some tetanic spasm of the jaws, but it could easily be overcome. The eyes were closed and on raising the lids I found that there was divergent strabismus. There was no opisthotonos or any approach to it and the legs were *not* affected by the convulsions. She had another convulsive attack after I had seen her. She died the next day. The coma lasted to the end. A fatal result during tetany must be of rare occurrence. A peculiar feature about the cortical irritation was, that though bilaterally the leg centres are so close together, they were not affected by the convulsions, which emanated chiefly from the centres for the facial and ocular muscles and the arms and hands. The cortical discharges apparently did not spread upwards or across by the callosal fibres.

Enfield.

CASE OF MULTIPLE EPITHELIOMA OF THE TONGUE IN A WOMAN, AGED TWENTY-FIVE YEARS, RESULTING IN SPONTANEOUS AMPUTATION OF THE GREATER PART OF THE ORGAN.

By T. E. HAYWARD, M.B. Lond., F.R.C.S. Eng.,

AND

R. G. HENDERSON, M.A., M.B., Ch.B. Aberd.

The following case presents so many points of interest that we feel it ought to be put on record. As the patient only came under our notice in the later months of the disease we are unable to vouch for the early history of the case, but the facts as gathered from herself and friends are as follows.

About the beginning of 1900 or the end of the previous year the patient, then about 24½ years of age, noticed a blister on the left border of the tongue opposite the molar teeth. The blister was irritated by the adjacent tooth and broke, a small sore resulting which was very painful. For some months, however, she paid little attention to this and in the meantime, having become pregnant, medical advice was further postponed till after the birth of the child. She then consulted a medical man who advised removal of several teeth and this was done in a provincial infirmary last December. At the same time a portion of the ulcer, which she describes as being "only a small opening then," was removed and examined and was stated to be "not cancer." She was given a mouth-wash but no medicine. The ulcer, however, now got rapidly larger and after a stay of three weeks in the institution she went out feeling rather worse than before. On March 23rd of the present year the patient came under our notice for the first time suffering from severe arterial bleeding from the mouth. This proceeded from a huge ulcer of the tongue about the middle of the left border or rather farther back. The ulcer appeared as a deep cavern about half an inch in diameter at the surface and an inch or more in depth, its direction being down and in towards the hyoid bone. The base could not be seen on account of its great depth but could be felt with the finger and from the base the bleeding appeared to proceed. The walls of the ulcer were even, firm, but not indurated, while the margin was clean cut, perhaps a little raised, but not indurated or everted. The bleeding was stopped by packing with gauze moistened with turpentine and perchloride of iron.

The diagnosis at this stage was difficult. The patient was a young married woman, aged 25 years, the mother of three healthy children and of good previous health, although now rather pale and poorly nourished. She had never had a miscarriage or anything to indicate syphilitic infection. Her family history was excellent. Her parents and grandparents were still alive and were known to us as particularly healthy people. A remote family history of cancer was, however, obtained: (1) the patient's great-grandfather (grandfather's father) died from cancer; and (2) a nephew of her grandmother died from cancer of the lip, aged about 50 years, attributed to the use of a clay pipe. A slight taint would therefore, appear to be present in both grandparents which we mention for what it is worth. The pain from the ulcer was only *moderate*; the discharge was slight and fœtid. The jaw appeared to be slightly swollen on that side and a small gland was felt under it. The diagnosis we considered uncertain, but we put the patient on anti-syphilitic and tonic treatment, together with an antiseptic alkaline mouth-wash. On March 25th the patient was suffering intense pain on the right side of the tongue, especially on attempts to swallow; this had been present, more or less, for two days, but was now much worse. She attributed it to the manipulation in packing the ulcer two days before when the tongue was pushed to the right side and irritated by a sharp tooth. This we found to be the case. There was an acute inflammatory swelling of the size of a large pea, very red and tender, on the border of the tongue, while the adjacent tooth had a sharp ragged edge. This tooth was removed on the following day, together with one on the opposite side which it was thought might irritate the ulcer. On the 29th it was noted that the ulcer was getting smaller. The inflammatory swelling on the right side was also rather smaller and the pain was almost gone. The swelling was paler in colour also, and at one part the pale, semi-translucent appearance, together with the increased hardness, suggested malignancy. On April 1st the ulcer was noted as getting smaller, but the walls appeared more roughly irregular. The tongue moved as if it would break across if pushed to the right. The swelling on the right side had not disappeared, but was now pale and hard and had begun to ulcerate on the summit. On the 19th the swelling on the right side had ulcerated deeply, so that there was now a cleft extending across the right half of the tongue towards the original ulcer. Behind and in front the cleft was bounded by a raised hard ridge of clearly malignant character. On this day also the patient complained of pain in the floor of the mouth under the fore part of the tongue. She had felt it slightly for a day or two. On examination a narrow transverse ulcer was found in the region of the frænum. This ulcer was malignant in character but quite distinct from either of the other two. The disease now made rapid progress. The cleft on the right side extended across to join the large ulcer on the left, so that the tongue appeared to be divided into two parts by a deep ulcerating trench running horizontally across the dorsum about its middle. The possibility of relief by operation had been suggested to the patient some time before but was not urged as we considered neither the local nor general conditions favourable. At our request, however, she entered the Liverpool Royal Infirmary on April 27th under the care of Mr. F. T. Paul, but operation was considered undesirable and she returned home in a few days. On May 4th the anterior portion of the tongue became detached, a result we had expected for some time. There was no bleeding. The patient, who had felt it getting loose for a day or two, simply lifted it out of the mouth without any severance of tissue. The detached portion was received the following day. It measured one inch long from tip to base and one and a quarter inches broad at the base which was slightly oblique. The under surface was ulcerated. The extreme tip had become black from commencing gangrene. The floor of the mouth now presented in front a dirty grey nodular area, limited behind by an ulcerating overhanging wall which represented the free edge of the root of the tongue. The increased pain now called for large doses of opium, and this for a time had the effect of slightly improving the patient's general condition which was very miserable, and also we feel sure of checking to some extent the local disease. Life dragged on till June 15th, when she succumbed to the extreme exhaustion from pain, lack of nourishment and the effects of occasional large hæmorrhages. Her age at death was 26 years and one month. A few days before her death the local condition was as follows. A deep excavation ran alongside the left ramus of the jaw, extending back to involve the fauces and tonsil. The bone itself was carious and thickened on the same side. On the right side the ulceration was less deep. The floor of the mouth was flat and firmly nodular in front while behind the root of the tongue was represented by a low mound of tissue with a median depression permitting a full view of the pharynx. The general emaciation was extreme. The total duration of the illness was about 18 months. Although the clinical features had for long left no doubt as to the diagnosis a portion of tissue was sent for examination to the Clinical Research Association who reported: "The sections show a typical squamous celled epithelioma of the tongue which has already invaded the muscular tissue. There is no evidence of any previous syphilitic lesion. The age and sex of this patient are very exceptional."

Remarks.—We have confined our account chiefly to the local features of the case as these were of the most peculiar interest. The pain, salivation, difficulties of feeding, and general distress were such as occur in every case of advanced cancer of the tongue. A few points however call for special remark. First, as to age and sex. Cancer of the tongue is decidedly rare under 30 years of age. Butlin[1] refers to the few recorded cases: three in males and three in females. In the present case the trouble began about the age of 24½ years and lasted about 18 months, but we are doubtful whether it was malignant from the beginning. It is also a curious fact that whereas of cases of cancer of the tongue in general only about 15 per cent. are women, yet when the disease occurs under the age of 30 years it affects the sexes equally. Then as to the multiple character of the lesions. We had here three distinct centres of malignant ulceration: first, the original large ulcer; secondly, the acute inflammatory swelling on the right border of the tongue, which from day to day we watched gradually assume malignant characters and from which the fragment for microscopical examination was taken; and thirdly, that beginning on the frenum and extending backwards. Each of them was clinically malignant although a portion of one only was submitted to microscopical examination. Butlin[2] states that a good number of double epitheliomas have been recorded but that the number two has not been exceeded. We think in the present case that there were three and to a certain extent we can explain their occurrence. Assuming, as we must, that in this patient there existed some overwhelming tendency to cancerous disease we would expect it, like other pathological conditions, to attack spots of lowered tissue vitality. This was clearly so on the right border of the tongue where a sharp tooth caused an acute inflammatory swelling—a common enough occurrence; however, although the cause was removed the effect did not disappear but became gradually transformed into a malignant tumour. So with regard to the frenum. The constant soaking in an extremely irritating and possibly infective discharge would undoubtedly lower its vitality and hence it succumbed. Thirdly, the combined effect of these lesions in producing a spontaneous amputation of the greater part of the tongue must be, we imagine, a very unusual occurrence. We have not seen a description of anything similar. The way in which it was brought about was very simple. The two ulcers on the opposite borders of the tongue gradually united across the dorsum and then formed a deep vertical trench across the tongue, which was met by the third ulcer extending backwards from the frenum along the floor of the mouth.

Finally, as to the treatment little need be said. Anti-syphilitic measures although they appeared to bring about improvement at first were discarded after a few weeks. Fœtor was combated by an antiseptic mouth wash. Pain was allayed by a paint of β eucaine locally and opium internally. We believe that the free use of opium in the later stages prolonged the life of this patient by about two months.

Haslock, Lancashire.

A CASE OF EXTENSIVE ENTERECTOMY.

BY ARTHUR E. BARKER, F.R.C.S. ENG.,

PROFESSOR OF THE PRINCIPLES AND PRACTICE OF SURGERY AT UNIVERSITY COLLEGE AND SURGEON TO UNIVERSITY COLLEGE HOSPITAL, LONDON.

THE following case illustrates a very dangerous sequel to an ordinary simple strangulated femoral hernia operated on in the usual way and its cure by extensive enterectomy. It also suggests some questions bearing upon the general treatment of cases of severe strangulation without actual gangrene.

The patient, a married woman aged 39 years, was admitted into University College Hospital on July 1st, 1900. Her personal and family history was good. She had suffered from a right femoral hernia of moderate size for four or five months which had come down during a bad fit of coughing. It gave but little pain or other trouble and always returned on lying down. On the afternoon of June 30th, some 18 hours before admission, the hernia came down while the patient was walking in the garden and caused great pain all over the abdomen and the back which was continuous. At 9 P.M. she vomited and at intervals during the night. She took some castor oil but it returned at once. On one occasion the vomit contained a little dark blood. The next morning (July 1st) she was admitted and I operated at once. The usual incision was made and when the sac was opened a good deal of fluid of high colour and foul smell escaped. The gut was dark, congested, and œdematous, but it retained its lustre. Both sac and gut were now carefully washed before the constriction was divided. The bowel was then drawn down and examined for further damage but none was found. As the œdema of the loop soon began to disappear when released and as the circulation seemed good it was washed, dried, and reduced into the abdomen. The usual radical cure was then done and the wound in the soft parts was closed without drainage. Recovery was rapid and uneventful except for flatulence. The bowels acted unaided on the sixth day and subsequently. There was no sickness after the operation but there was some pain in the abdomen.

The stitches in the skin wound were removed on the tenth day when perfect primary union was found. The patient left the hospital perfectly well on the sixteenth day for Brixton. Some weeks later I heard from her medical attendant, Dr. Horden, that she had a severe attack of intestinal obstruction with great pain on vomiting. This passed off, however, under his skilful treatment with opium, enemata, and fomentations and she was able towards the end of August to return home to Cornwall. But before doing so she called at the hospital to show herself and she then seemed to be in excellent condition. At the beginning of October, 1900, I had a letter from her medical attendant, Dr. F. Hichens of Redruth, to say that on Sept. 9th she had been attacked again suddenly with intestinal obstruction in a very severe form with great pain starting in the right groin and spreading all over the abdomen with vomiting and distension, so that he feared for her life so great was the collapse and so extensive the peritonitis. His very thoughtful treatment was, however, followed by recovery. His object in writing was to suggest exploration of the abdomen as it seemed beyond doubt that there must be a kink or adhesion or both about the point of the bowel which was originally involved in the hernia. The patient returned to London with this object in view and she was re-admitted on Oct. 13th, 1900. She now appeared to be in good health, but she gave a history of great constipation alternating with diarrhœa ever since the first operation, combined with much flatulence. Since the last attack on Sept. 9th she had only to complain of irregular bowels, flatulence, and irregular and painful spasms on the right side of the abdomen. On examination there was no trace of the return of the hernia at the seat of the first operation and no tenderness was there. The abdomen was generally soft, but there was some tenderness in the right iliac fossa on deep pressure and there were some indefinite thickening and resistance as well. Nothing abnormal was found otherwise in the abdomen.

---

[1] Butlin and Spencer: Diseases of the Tongue, second edition, p. 312.

[2] Op. cit., p. [illegible]

[1] A paper read before the Medical Society of London on April 22nd, 1901.

Taking the view that there must be either a kink at the original seat of hernial strangulation or bands of adhesion or both together I opened the abdomen (on Oct. 19th) by an incision along the outer border of the right rectus muscle. It was at once seen that the intestine was matted together round the knuckle of intestine originally in the hernia by many firm adhesions which fixed it in the position to which it had been returned. It was sharply kinked and soldered up into one mass in this position. The adhesions spread for a considerable distance around and one loop a foot from the kink was fixed by a strong band out of sight on the *left* side of the abdomen. To reach this I had partially to divide the right rectus muscle transversely from without and then only with the greatest difficulty could this band, which was about as thick as a goose-quill be separated from the bowel. An attempt was now made to undo the kink but it only resulted in opening the damaged, softened intestine. I therefore closed the intestine above and below all the portions involved in the matted adhesions in the Doyen's forceps and removed the whole mass, cutting the mesentery close to the intestinal attachment. The cut ends of the intestine were now united end to end in the usual way by two rows of fine silk sutures—a deep and a superficial. The hole in the mesentery was also closed and the area of operation was dried out. The transverse cut in the rectus muscle was stitched up with buried sutures, as also was the upper part of the vertical incision. The lower part of the latter was left open to hold a gauze drain for a few days.

The patient bore the operation very well and convalescence was uneventful, except for a slight rise of temperature for the first few days, until the gauze drain had been removed. She had been rather collapsed on the evening of operation, but she recovered rapidly under saline injections under the skin and rectal injections of brandy-and-water. The bowels acted well on the fifth day naturally and almost daily subsequently. The superficial wound healed per primam except at the lower angle where the drainage gauze lay and at the upper angle where there was some serum pent up in the fat. She was fed by the mouth with small quantities of albumin water from the second day onwards and was soon taking solids. At no time was there any trace of fæces in the drainage from the lower angle of the wound. The patient returned home to Cornwall just before Christmas quite well.

The following is the surgical registrar's description of the parts removed :—

> The length of the small intestine removed was ascertained by the curator to be 37 inches. The upper seven inches above the obstruction was hypertrophied and dilated. The chief narrowing consisted of an atrophied fibrous shrinking of the bowel, reducing its lumen to the size of a cedar pencil, at one spot about one-third of an inch in length. Immediately around this and for eight inches below the bowel is irregularly distorted by adhesions which matted it together during its stay in the abdomen. Towards the lower end there are several more adhesions which do not distort the gut.

This case must, I think, have a certain interest for all surgeons, whether in general or in special practice. It illustrates the need of an early operation in all cases of strangulated hernia. It also shows that although a relatively early operation may be done and be immediately as successful as any such measure can be all dangers are not necessarily thereby prevented. In this case we know certainly the moment at which the strangulation began. We know that the herniotomy was performed about 18 hours later. We know that the bowel although discoloured showed active circulation and no lymph upon its surface. And yet, though the recovery was perfect from the reduction and the radical cure, a most serious condition of things was left in the abdomen which led to two severe and nearly fatal attacks of intestinal obstruction and ultimately required one of the most serious operations in surgery. The first herniotomy was quickly over and it involved no great exposure of the gut to manipulation. It was such as one constantly does without misgiving, and yet the changes induced in the bowel by the strangulation were very grave. Fortunately, the subsequent attacks of obstruction were under the care of two highly skilful general practitioners who not only treated them with the utmost judgment but also recognised with promptness the need of subsequent surgical interference. It is also fortunate that now in enterectomy we have a means of remedying such conditions as result from kinks and adhesions without such severe risks as were formerly bound up with excision of the intestine.

Harley-street, W.

PRELIMINARY NOTE ON THE DIRECTION OF THE AIR CURRENTS IN NASAL RESPIRATION.

BY CHARLES A. PARKER, F.R.C.S. EDIN.,
SURGEON TO THE HOSPITAL FOR DISEASES OF THE THROAT,
GOLDEN-SQUARE.

OBSERVATIONS were carried out in order to determine the exact course which the air takes within the nose during nasal inspiration and expiration. The method employed for inspiration was that of impregnating the air with lycopodium by means of an insufflator held about eight inches from the nose both during quiet and forcible inspiration, and then noticing the disposition of the powder within the nasal cavities. For expiration the gentle, and afterwards the forcible, exhalation of tobacco-smoke through the nostrils was carefully observed during rhinoscopic examination.

The results of these observations show that in normal noses during quiet inspiration the powder impinges on the septum about half an inch within the nostrils and a third of an inch above the floor, and is then carried upwards and backwards in a broad band into the middle and superior meatus, entirely missing the inferior passage and lower turbinate. After deep and forcible inspiration the powder takes the same course and is, in addition, seen to be deposited round the upper part of the posterior choanæ, the upper fourth of the septum, and on the roof of the post-nasal space. It is also carried down the middle of the posterior wall of the oro-pharynx, coming to a point about the centre, from which spot it takes a straight course into the larynx, impinging on the arytenoids but missing the epiglottis. In expiration the smoke when gently exhaled passes chiefly through the inferior meatus—that is, below the upper level of the inferior turbinate. In forcible exhalation some smoke passes through the middle meatus as well as the lower.

In abnormal nares any irregularities, such as spurs, deviations, enlargements, and hypertrophies of the inferior turbinated bodies, &c., which prevent the passage of air from the vestibule to the middle meatus will become covered with powder and divert its course in a manner varying with the exact position and extent of the irregularity. Most spurs and enlargements of the inferior turbinate are situated too low to intercept the inspired powder; deviations of the septum, polypi, and enlargements of the middle turbinate, on the other hand, become thickly coated with powder. In expiration complete blocking of the inferior meatus diverts the smoke into the middle meatus, from which it issues slowly and diffusely instead of in a straight compact stream as seen when it comes through the inferior meatus in a normal nose. Spurs, as a rule, split the stream, so that some comes below it through the inferior meatus and some above it through the middle passage, in which case they apparently cause no difficulty to expiration.

In cases of adenoid hypertrophy where the growth is slight the powder takes the usual course in the anterior nares, but collects between the septum and the growths and around the posterior choanæ. In bad cases the powder takes a lower course than in a normal nose, being seen resting chiefly on the inner and upper surfaces of the inferior turbinate and on the lower part of the septum. Expiration is not as a rule interfered with. In no case of either normal or abnormal nares was any powder seen on the under surface of the lower turbinate or along the floor of the nose.

From these observations it may be gathered that during quiet inspiration in a normal nose the air traverses the middle, the superior, and probably the fourth meatus, and never the inferior meatus. This makes it a little difficult to explain how the inferior turbinates perform their function of warming and moistening the air, but renders the stimulation of the olfactory nerve endings easily explicable. As regards spurs and deviations of the septum and enlargements of the inferior turbinates it seems that they only interfere with inspiration when they are in the way of the entrance of air into the middle meatus. Polypi or enlargements of the middle turbinates, on the contrary, considerably interfere with easy inspiration. Hypertrophies and growths springing from the roof of the naso-pharynx will also cause considerable obstruction to inspiration, being in the direct air way. It may also be concluded that in expiration the air traverses the inferior meatus chiefly and that any hypertrophies or deformities causing stenosis of this passage will render expiration uncomfortable and difficult. In conclusion it may be noted that the use of lycopodium as above described may be applied for practical purposes. The powder will be freely deposited on any irregularity which is causing obstruction and which should be removed, and, conversely, if a spur, for example, is left untouched by the powder it may be left alone as far as respiration is concerned, unless it is sufficiently large to interfere with expiration, which is not often the case.

ST. GEORGE'S HOSPITAL.

A CASE OF HÆMORRHAGIC TYPHOID FEVER.

(Under the care of Dr. W. EWART.)

FOR the notes of the case we are indebted to Dr. Lee Dickinson.

A woman, aged 29 years, was admitted into St. George's Hospital on Nov. 18th, 1892, under the care of Dr. Ewart. The family history was good and there was nothing upon the most careful inquiry that could be construed into inheritance of hæmophilia. The patient, indeed, had been liable to somewhat profuse menstruation for the last seven years, but there were no other hæmorrhages and the general health was fairly good. The only serious illness remembered was an attack of pleurisy on each side in succession in 1886; the left pleura was aspirated and she made a good recovery. There was no suspicion of alcoholism.

The patient was sent to the hospital as a case of typhoid fever of about 12 days' duration, the leading symptoms having been headache, perspirations, and disturbed sleep. Spots had been found four days before admission. When the patient was admitted she was somewhat anæmic and rather too fat, but she was not profoundly impressed by her illness, and there seemed to be no reason why she should not make a good recovery. The diagnosis of typhoid fever was fully confirmed. There were several rose spots on the abdomen at the time of admission and a few spots were observed as late as Dec. 7th. The bowels were at first confined. The temperature was irregular but never very high; it reached 103° F. on more than one occasion and averaged about two degrees lower. As regards the hæmorrhages, the first to be observed was a moderate loss per vaginam, which was present on admission and continued to within a week of death. Early on Dec. 12th severe hæmorrhage from the gums set in and later in the day a copious motion was passed consisting largely of red blood. Saccharated lime, gallic acid, and the usual remedies for intestinal hæmorrhage were employed, but blood continued to pass from the bowel, though not in large [illegible] appeared on the skin, a con- [illegible] ght eye and others beneath [illegible] 15th the urine was loaded with corpuscular bloo[illegible] ased. The retinæ were free [illegible] blood from the finger flowe[illegible] and was of pink colour [illegible] blood of pernicious anæm[illegible] ously diminished in number and individually rich in hæmoglobin. The leucocytes were considerably increased, and on one or two occasions granular masses of pigment were seen. The first copious hæmorrhage from the bowel was followed by a rise of pulse-rate from 112 to 140 and a general change for the worse in the patient; it had been apparent, however, for some days that the weakness was greater and the anæmia more intense than so mild an attack of typhoid fever would itself account for. Eventually she became extremely blanched and died from exhaustion on Dec. 18th.

Necropsy.—At the post-mortem examination, which was made by Dr. H. D. Rolleston, the blood was found to be generally fluid though the cavities of the heart contained pale clots. The pleural cavities were closed by old adhesions, but the pericardium and peritoneum showed numerous petechiæ, and beneath the endocardium of the right auricle was an extensive hæmorrhage. Hæmorrhages were found also under the capsules of the liver and spleen, under the mucous coats of the bladder and stomach, in the pelves of both kidneys, and in the right Fallopian tube. In the ileo-cæcal region there were many ulcers, some of which were not far from perforation. These ulcers were undoubtedly of typhoid origin, though the edges were less infiltrated and undermined than usual. The colon and rectum were vividly injected but were not ulcerated.

Remarks by Dr. LEE DICKINSON.—In THE LANCET of April 20th, 1901, p. 1156, there is an interesting annotation upon a paper by Dr. A. E. Eshner and Dr. T. H. Weisenberg in the *American Journal of the Medical Sciences* for March on Hæmorrhagic Typhoid Fever. The paper describes two cases of this exceedingly rare complication of typhoid fever and the annotation suggests that alcohol, to which both the patients were addicted, was an important contributory cause of the hæmorrhagic condition. The above case may therefore be of interest for it was a marked example of hæmorrhagic typhoid fever and one, moreover, into which the alcoholic factor did not enter. It seems equally certain that true hæmophilia may be excluded in so far as the term "hæmophilia" connotes a congenital tendency to hæmorrhage, but that many and various hæmorrhages took place and that they were in some way connected with the typhoid fever and directly dependent upon deficient coagulability of the blood is beyond all question.

The case occurred nearly nine years ago, since when certain therapeutic advances have been made in the direction of promoting the coagulative power of the blood when deficient, but whether the administration of any such substances as calcium chloride, nucleo-proteid, gelatin, and the like can be of material use when, as seems probable, the cause of the hæmorrhagic condition is a toxin in the blood may well be held as doubtful. In the future we may perhaps look more hopefully to some form of antitoxin treatment which will so far surpass the treatment at present in vogue for the prevention of typhoid fever as to neutralise at once the established disease and the general tendency to hæmorrhage, which is one of its rarest and most terrible dangers. Although the case is barren as regards therapeutic suggestion it seems to the point on the present occasion and for this reason I venture to submit it to the profession. I am indebted to Dr. Ewart for kindly allowing me to make use of the clinical records of the above case for which, as medical registrar at the time, I am entirely responsible.

SOUTH DEVON AND EAST CORNWALL HOSPITAL.

A SUCCESSFUL CASE OF LAPAROTOMY FOR INTUSSUSCEPTION.

(Under the care of Mr. C. WHIPPLE.)

THE value of early operation in intussusception is now generally acknowledged, and the increasing number of cases recorded confirms it. If we were to judge of the mortality after the operation by the cases published a decidedly erroneous opinion would be formed, for in this as in most other operations a larger proportion of the successful than of the unsuccessful cases find their way into print. If we take all the cases in a large hospital in which an operation is performed for intussusception we find a death-rate which is decidedly higher than that based on recorded cases. The mortality after operation need not deter us from operating, though it should impress on us the need of early operation, for the death-rate increases with the duration of the invagination.

A girl, aged two years, was admitted into the South Devon and East Cornwall Hospital on May 30th, 1901, for vomiting and abdominal pain. The history of the case was that she had been suffering from "ulcerated bowels" for the previous fortnight. On May 29th, about 9 P.M., the child was attacked with sudden acute abdominal pain; she cried a good deal and vomited. On the 30th, about 3 A.M., the bowels acted, the motion being dark and slimy, "like tar." The patient passed two similar motions afterwards, the second being at 3 P.M. The vomiting continued up to the time of admission in the evening.

On examination the abdomen was found to be slightly distended and tense from muscular action, but a firm elongated mass of characteristic "sausage"-shape could be felt in the situation of the transverse colon. Nothing abnormal was found on rectal examination. The pulse was 94 and the temperature was 99° F. At 10 o'clock the child was anæsthetised with chloroform (later in the operation a little ether was given). When under its influence the mass could be distinctly defined extending towards the right loin. The abdomen was opened by a three-inch incision slightly to the right of the middle line and the mass was drawn out on to a warm sterilised towel: it was found to be an ileo-cæcal intussusception. Reduction was effected with slight difficulty, a small peritoneal tear in the ascending colon requiring two Lembert's silk sutures. There were considerable œdema and a little lymph about the cæcum. About six inches of ileum and six inches of cæcum and ascending colon were intussuscepted. The extruded portions of bowel were washed in warm sterile saline solution and returned to the peritoneal cavity. The peritoneal incision was then closed with a continuous catgut suture and the wound in the abdominal wall was closed with interrupted sutures of salmon gut. The operation lasted 20 minutes. On May 31st the morning temperature was 101·6° and the evening temperature was 98°. The child's bowels acted twice, the motions being loose and yellowish. She was fed with two drachms of milk with two drachms of hot water every hour. On June 1st the temperature was normal. As the child cried a little boiled soft bread was added to the milk-and-water, the quantity of which was doubled. The bowels acted three times. On the 3rd the diet consisted of boiled bread with milk and tapioca pudding and milk. The bowels had acted once. On the 6th the wound was dressed and was found to be soundly healed; the stitches were removed.

Remarks by Dr. H. W. WEBBER.—I am indebted to Mr. Whipple for permission to operate on this case and to record the notes, and I am glad to be able to add one more to the number of successful laparotomies for intussusception. Operative treatment seemed to be distinctly indicated in this case as the condition had lasted 25 hours, by which time adhesion between the peritoneal surfaces would be commencing and œdema present—as was actually found, and the child's good pulse and general condition gave hopes that she would bear the operation well.

Medical Societies.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

Resection of the Intestine.—General Paralysis of the Insane.

A MEETING of this society was held on June 5th, Dr. A. G. MILLER, the President, being in the chair.

Dr. F. M. CAIRD read a paper on Resection and Suture of the Intestine, with special reference to Strictures of the Large Intestine. This communication might be regarded as supplementary to one read in the society in 1895 (Vol. xiv. of the Transactions) and was intended to give the results of further experience.

Dr. LEWIS C. BRUCE of Murthly Asylum read a paper on Clinical and Experimental Observations upon General Paralysis. It was necessary, he said, to define general paralysis as a disease marked by progressive degeneration of all the bodily and mental functions, commencing first with those most highly developed and recently acquired and ending with complete wreckage of mind and body. The course of the disease varied greatly according to individual resistance. Some showed mental symptoms before motor symptoms became prominent, while others presented motor symptoms sometimes for years before any mental peculiarities developed. The disease was regarded as incurable, but remissions often of a very complete nature were by no means uncommon. The typical disease was further peculiar in having several stages: (1) the first stage, in which the patient was often acutely ill with febrile temperature, loss of body weight, restlessness, excitement, and sleeplessness; (2) the second stage, in which he became fat, facile, lazy, and liable to congestive seizures; and (3) the third stage in which the patient again lost weight and became mentally demented and physically paralysed. The opinion that syphilis, if not the only cause, was certainly one of the chief, was at present gaining ground both in this country and abroad. The following observations were made upon patients suffering from undoubted general paralysis and might be classified as (1) those observations made on patients where the disease was steadily progressive; (2) those made in patients in a state of remission; and (3) those concerned in an attempt to produce remission. 1. In those in whom the disease was progressive the system which Dr. Bruce believed to be invariably affected throughout the whole course of the disease was the alimentary system. He had never met with a case in which there were not intestinal or gastric disturbances. In the second stage bulimia was generally added to the symptoms of the first stage, while in the third and last stage constipation alternately with diarrhœa was the rule. The significance of these symptoms had not been appreciated nor had it been realised that they ran from the beginning to the end of the disease, as they were so often masked by the mental symptoms. After quoting various authorities regarding the temperature in cases of general paralysis Dr. Bruce stated that he had carefully observed the temperatures of such cases for several years, making continuous charts of from four to six months' duration. In some few steadily progressive cases the temperature never rose above the normal. In others the temperature was irregular, febrile attacks occurring at long intervals. Such might be explained by the powers of individual resistance. As a result of his observations he supported strongly Dr. McPherson's opinion that the most characteristic temperature in general paralysis was the recurrent febrile attack every one or two weeks. On admission of the patient there was probably a febrile temperature of about a week's duration; then there was a remission for about three weeks, when again there was a febrile attack with or without mental symptoms, followed in turn by a remission of a month's duration it might be. When the second stage was established these febrile attacks became more frequent and the remissions shorter. As this stage passed slowly into the third stage the temperature tended to become subnormal, the febrile attacks of the second stage being represented by a gradual rise from subnormal to normal. The explanation was that the patient was becoming exhausted and did not react so vigorously as before. When the third stage was fairly entered the temperature became very irregular (the consideration of fever due to congestive seizures or apoplectiform attacks was purposely omitted as merely complicating matters). The constant recurrence of such febrile attacks could only be regarded as being due to some recurrent cause and that a toxic cause. Each febrile attack represented the resistive reaction of the body to some toxic substance and each interfebrile period an intermission when the resistive powers of the patient had subdued the action of the toxin. Kanthack considered it a rule that "previous to recovery from bacterial products an increase in the number of leucocytes takes place." Dr. Bruce counted the leucocytes and took the temperature daily of some six cases of general paralysis for three or four months continuously and a glance at the charts showed that every rise of the thermometer occurred with a similar rise in leucocytes. In the first stage the hyper-leucocytosis was often very great, being from 20,000 to 30,000 per cubic millimetre, and the higher and larger the leucocytosis the longer was the remission that followed the attack. In the second and early third stage the leucocytes still rose with each rise of temperature, but the reaction was not so vigorous and the remissions were shorter. In the later period of the third stage the leucocytosis resembled the temperature in being very irregular but not necessarily coinciding. There were practically no periods of remission. Even in those progressive cases where there were no recurrent febrile attacks there were still occasional instances of hyperleucocytosis. These latter coincided with periods of advance in the disease, and following on these periods of hyperleucocytosis there were remissions just as happened in those cases with febrile attacks. In one case of acute early general paralysis Dr. Bruce, while examining a fresh specimen of blood, found a motile bacillus. A film specimen showed apparent streptococci. Dr. Ford Robertson confirmed these observations. The urine of this patient contained blood and in it was found the same motile organism. This was the only case of general paralysis in which Dr. Bruce had found living organisms in the blood. He regarded it as an accidental occurrence, but one which might occur much more frequently than was supposed. As this motile bacillus resembled the bacillus coli Dr. Bruce tested the blood serum of the cases of general paralysis to see if they had the power of agglutinating bacillus coli. The serum from 10 such cases was tested in dilutions varying from one in five to one in 20 and no reaction was obtained. 2. Observations made upon patients in a state of remission had to be divided as follows: (1) remissions which followed upon acute attacks of intercurrent disease, as after erysipelas of the scalp, pneumonia, carbuncle, &c. Such were preceded by a high and continued hyper-leucocytosis. (2) Remissions which occurred naturally and without obvious cause during the course of the disease. In those cases where Dr. Bruce had observed actual improvement to take place he noted that the powers of the alimentary system improved. The temperature was never febrile, but the chief feature was that the number of leucocytes in the early stage of the remission rose higher than they were in ordinary health (from 9000 to 12,000 per cubic millimetre). As the remission became fairly established the leucocytosis gradually fell to that of ordinary health. The serum also of such cases contained some antitoxic substance which was not present in patients in whom the disease was progressive or in the serum of healthy persons. The power of the blood serum to agglutinate bacillus coli in dilutions varying from 1 in 5 to 1 in 20 was tested in 10 cases in states of remission and seven gave a definite agglutinative reaction. Nature then appeared to check the disease and produce remissions by firstly producing a hyper-leucocytosis, the leucocytes in their turn producing some substance of the nature of an antitoxin in the blood which protected for a limited time against further doses of the toxin. 3. In attempts to produce remission the observations which Dr. Bruce made led him to believe that the majority of cases of general paralysis were due to toxic poisoning derived from bacteria and absorbed through the stomach or intestines He believed that each febrile attack represented the actual entrance of bacteria or their toxins into the blood or tissues and that during the remission periods the blood must possess some antitoxic substance. He tested the truth of this as follows. A patient suffering from general paralysis in the second stage and during a well-marked remission had an attack of lumbago. This patient was wet cupped with antiseptic precautions and the blood so obtained was defibrinated. Two earlier and progressive cases of general paralysis were placed in bed and into each were subcutaneously injected two cubic centimetres of this defibrinated blood daily for three weeks. Patient No 1 was in the early first stage; patient No. 2 was in the early period of the second stage. Patient No. 1 became so far recovered that his friends insisted on his discharge and he accordingly left the asylum. The treatment was adopted two years ago, and though his mental condition was impaired this patient could support himself as a saddler and had done so since his discharge Case No. 2 had shown physical but no mental improvement, though the progress of the disease in his case had been definitely arrested for nearly two years. Four other cases of general paralysis, contemporaries of these two so treated patients, were now dead, and it was suggestive that these two men should have given the reaction they had done to treatment. It was obviously impossible to continue treatment on these lines, but Dr. Bruce believed that the blood of patients in conditions of remission could agglutinate the bacillus coli, that small subcutaneous injections of blood serum from a horse immunised to bacillus coli continued for from three to four weeks might produce artificial remission in the disease, and Dr. Bruce was giving this treatment a trial. His conclusions were (1) that general paralysis was a disease directly due to poisoning by the toxins of bacteria whose point of attack was through the gastric and intestinal mucous membrane; (2) that the poisoning was probably a mixed one, but that the bacillus coli was apparently one of the noxious organisms; and (3) that the result of treatment with serum taken from a case of general paralysis in a condition of remission and injected subcutaneously into an early progressive case pointed strongly to the fact that some form of serum treatment was the proper one for this disease.

Dr. Ford Robertson read a paper upon New Observations bearing upon the Question of the Pathogenesis of General Paralysis of the Insane. He stated that his own studies upon this question, pursued chiefly along the lines of pathological anatomy, lead him to conclusions in entire agreement with those formulated by Dr. Lewis C. Bruce. What was still disputed was not the fact of the toxic origin of the disease but only the mode in which the toxins acted. He explained the grounds upon which he was unable to agree with the conclusion of Mott and Krafft-Ebing. that general paralysis depended upon a premature involution of the cortical nerve cells, and he defended the opinion of Angiolella that the disease was the result of a chronic toxæmia which especially damaged the vessels of the central nervous system. The accumulated evidence in support of the latter view was now beyond all question exceedingly strong. The vessels of the central nervous system had special structural features which served to explain why they were specially prone to be injured by certain forms of chronic toxæmia. He referred to the numerous observations which showed that general paralysis had a remarkable association with various forms of bacterial infection. and that important gastro-intestinal disorders constantly accompanied the disease. He then described his own observations upon the condition of the liver and gastro-intestinal tract in a series of cases. In the liver there was constantly evidence of long-standing irritation of the fibrous tissues of the portal spaces. This fact pointed distinctly to the absorption of irritants from the alimentary tract. In all of 12 cases systematically examined he found various chronic lesions of either the stomach or intestines. Chief among these was a chronic catarrhal state of the stomach and duodenum and lower part of the ileum, associated with thickening and erosions of the mucous membrane. There was strong evidence that the changes observed were the result of the action of an irritant which bathed the internal surface He thought that the view that they were the result of the cerebral condition was quite untenable. Nevertheless, these gastro-intestinal changes were not the cause of general paralysis but the result of the same toxic action as that which gave rise to the other lesions in various parts of the body. When all the facts that had been ascertained were taken into account two conclusions seemed to him to be justified—namely (1), that the toxæmia of general paralysis was of gastro-intestinal origin, and (2) that the toxins were mainly bacterial. There was evidently a partial breakdown of those forces by which any harmful development of the intestinal organisms was normally prevented He discussed the question of how the inhibition of the growth of these bacteria was normally effected, and he insisted that the phenomenon could only be explained as essentially the result of the same forces as those by which the growth of bacteria was prevented in the living tissues—namely, by the action of leucocytes, alexins, and antitoxins. There was conclusive evidence that in the general paralytic, even at an early stage of his disease, there was a weakening of the natural resistance to bacteria or of the natural immunity Such weakened power of resistance would manifest itself specially in the alimentary tract in which the inhibitory substances were in a state of comparative dilution The toxæmia was probably in some measure established for months, or even years, before the first symptoms of nervous disease manifested themselves. In some individuals the cerebral vessels gave way earliest, and general paralysis was the result; in others, the vessels of the cord were the more vulnerable, those that received the largest quantity of blood and therefore of toxin suffered first and most severely, and the clinical and pathological picture of tabes dorsalis developed He advanced the hypothesis, against which he knew many as yet unanswerable arguments could easily be brought, that the alteration in the general immunity was dependent upon commencing exhaustion of the leuco-blastic functions of the bone marrow. He pointed out how this hypothesis would explain certain very contradictory facts regarding general paralysis and tabes. The factors which were known to favour the development of these two types of nervous disease were for the most part such as caused prolonged leucocytosis.

Dr. T. S Clouston said that the study of general paralysis was perhaps the most interesting in the whole range of medicine. He thought that the results of the work now laid before the society were (if substantiated further) epoch-making. For the first time in 40 years he had a feeling that this disease might be cured. He was not convinced that the disease was a vascular one but held it to be almost certainly proved that it was of a toxæmic nature. The disease seemed to begin in the highest centres of the brain and the progressive degeneration spread to every other centre of lower natures. He thought it was perfectly consistent with the toxæmic theory that the neurons were in the first place affected and the capillaries later.

Dr. BYROM BRAMWELL stated that syphilis was the most important element in the causation of general paralysis and tabes dorsalis, but some irritant or strain must be added to this to determine the disease. He thought that Dr. Bruce and Dr. Robertson were perhaps limiting the causation too much. It seemed to him that various forms of irritation might act on the nervous centres which had been already acted on by the syphilitic poison. Else why did the toxin not produce the disease in individuals who had not had syphilis?

Dr. WILLIAM RUSSELL said that a point of interest to him was the occurrence of leucocytosis during the febrile periods in the course of general paralysis. He regarded it as proof of a toxæmia. With regard to Dr. Robertson's contentions, there was a point which the pure pathologist was apt to overlook and that was the perturbation of function which preceded anatomical changes. In some cases he was satisfied that this occurred and that general paralysis supervened upon domestic and business worry with long days of work and short nights of rest and in persons, too, who never had syphilis. Following upon this functional perturbation came anatomical changes and he thought it very dangerous to assert, unless the evidence was very strong, that the vascular changes were primary and the surrounding sclerosis secondary. In various morbid conditions a local disturbance with the production of irritative products led to local endarteritic changes, and yet there might be no question at all that the vascular changes were secondary.

Dr. GULLAND, Dr. MCPHERSON, and Dr. JAMES RITCHIE also spoke and Dr. BRUCE and Dr. ROBERTSON replied.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—A meeting of this society was held at 20, Hanover-square, W., on June 26th, the President, Dr. A. J. Harrison, being in the chair.—Dr. H. Radcliffe Crocker proposed that a vote of condolence should be conveyed to the family of the late Dr. Cavafy on his death, and referred to the serious loss sustained by the society and by British dermatology in his death. The vote of condolence was passed unanimously by the meeting.—Dr. T. D. Savill showed a case of Bromide Eruption in a child, aged five and a half years, who had been under the care of Dr. Fletcher Beach and had been given 15-grain doses of potassium bromide thrice daily for 19 days.—Dr. Phineas S. Abraham showed: 1. A case of Lupus Vulgaris in a child, aged 13 years. The eruption had improved rapidly under treatment with x rays. 2. A second case of Lupus which had benefited by the same treatment.—Dr. E. G. Graham Little showed: 1. A case of Favus in a young lad, a Russian Jew; there were typical yellow scutula on the scalp and extensive loss of hair. 2. A case of Leucodermia and Melanodermia combined of four years' duration in a boy, aged 12 years. 3. A case of Hypertrophy of the Upper Lip in a boy aged 10 years; the swelling had been present for the last five months. There was a strong tuberculous history and it was possibly a tuberculous swelling. 4. A case of Multiple Lupus Vulgaris with a distribution and aspect of psoriasis and in addition an eruption of lichen scrofulosorum on both legs.—Dr. Graham Little also showed a microscopic specimen of a Favus Hair which was stained to demonstrate the invasion of the hair-shaft by the typical fungus.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—The following members have been elected as officers and councillors for the year 1901-1902:—President: Mr. W. A. Maggs. Vice-Presidents: Mr. A. S. Underwood, Mr. F. J. Bennett, and Mr. W. H. Woodruff (resident); Mr. G. Brunton (Leeds), Mr. W. S. Woodburn (Glasgow), and Mr. W. B. Bacon (Tunbridge Wells). (non-resident). Treasurer: Mr. C. F. Rilot. Librarian: Mr. H. Baldwin. Curator: Mr. J. F. Colyer. Editor of Transactions: Mr. H. Lloyd Williams. Honorary Secretaries: Mr. J. H. Mummery (Foreign), Mr. A. Hopewell Smith (Council), and Mr. W. Rushton (Society). Councillors: Mr. J. H. Reinhardt, Mr. H. G. Read, Mr. G. Northcroft, Mr. R. Wynne Rouw, Mr. J. Mansbridge, Mr. M. F. Hopson, Mr. Morton A. Smale, Mr. R. D. Pedley, and Mr. J. Percy Smith (resident); Mr. D. Corbett, jun. (Dublin), Mr. Rees Price (Glasgow), Mr. G. O. Whittaker (Manchester), Mr. T. Mansell (Birkenhead), Mr. W. A. Rhodes (Cambridge), Mr. W. Glaisby (York), Mr. J. J. H. Saunders (Barnstaple), Mr. E. A. Bogue (New York), and Mr. J. F. L. Pike (Sheffield), (non-resident).

Rebiews and Notices of Books.

A Text-book of Pharmacology and Therapeutics, or the Action of Drugs in Health and Disease. By ARTHUR R. CUSHNY, M.A., M.D. Aberd., Professor of Mater Medica and Therapeutics in the University of Michiga Second edition. London: Rebman, Limited. 190 Pp. 732. Price 17*s.* 6*d.* net.

WE noticed the first edition of Professor Cushny's work our issue of April 20th, p. 1146. There is but little more say about this, the second edition. Although the title on t cover is simply "A Text-book of Pharmacology," the titl page bearing the more extended name given above, yet t book deals with pharmacology, therapeutics, toxicology, a materia medica, but the interest is so largely centred up the first mentioned that it is quite an appropriate name select. The volume includes references to all the drugs a preparations which are official in the United States Pharm copœia and the British Pharmacopœia, and it is worthy note that preference is expressed for the use of the metr system, although both systems of weights and measures a given.

With regard to therapeutics the author's position is ve clearly stated. He treats the subject from the experiment standpoint and makes the results of the laboratory invest gator the basis of almost every statement, and he objects the use of such terms as "alterative" or "tonic" whic refer to hypothetical conditions which cannot be establish by direct experiment.

As a text-book of pharmacology this work is very comple and very satisfactory. The author has read widely and ha incorporated the results of his reading with admirab lucidity and brevity, while at the end of each section has enumerated references to more detailed sources information. His direct and dogmatic style should facilita the employment of this book by students, even though occasionally represents only one side of a disputed subjec The arrangement adopted is that of Buchheim an Schmiedeberg, the drugs being grouped into classes name from the most prominent member or from some marke property possessed by all. In this way much needles repetition is avoided and students instinctively recognis the more important facts concerning each individua member of the group, although the actions of each are full given.

The drugs selected are principally those which are officia and naturally the greatest space is devoted to those whic possess well-marked actions, such as quinine, digitalis atropine, and nux vomica. Although these are treated i great detail many of the newer remedies receive adequat recognition, as, for example, anhalonium, heroin, urotropi eucaine, and orthoform. On the other hand, the author caution is well shown in the following remarks (p. 683) upo some of the newer antiseptic astringents: "As with so man of the products of the new industrial chemistry, they ar thrown on the market in such profusion, and are heralde with such exaggerated praise, that it is impossible at presen to state which of them are really improvements on the mor generally recognised preparations, and which are merel adapted to enrich the inventor, without materially ad vancing therapeutics."

Professor Cushny is to be congratulated upon havin presented a difficult subject in an attractive manner This book should do much to promote an intellige scientific employment of drugs and to discourage antiquate empiricism which has so long retarded progress. The bo is well printed and is provided with a satisfacto

On Some Practical Methods of Sanitation in India, with Special Reference to Cantonments By ERNEST ROBERTS, D P H Cantab, Major, I M S Reprinted from the Scientific Memoirs by Medical Officers of the Army of India, Part XII Simla: Printed at the Government Central Printing Office 1901

THE introduction of a system of treating sewage after the method pursued by nature and on what may be termed biological principles has been one of the practical results attending the investigation of the rôle played by mixed communities of micro-organisms in their action on the waste organic matter which is continually being received upon the surface of the earth in order to restore it to its original elements Nature's method is effected, as we know now, in two stages—by the breaking down and liquefying of the solid organic matter and by the subsequent nitrification or mineralising of the results thus obtained Both are accomplished by the instrumentality of organisms consisting of anaerobia and aerobia, according as oxygen is essential or not to their existence While both classes of organisms share in the liquefying process it is the latter (the oxygen-requiring organisms) that alone do the work of nitrifying or mineralising the liquefied sewage products

The object which the author has in view is, in the first place, to review the practical methods of sanitation in vogue in India and to examine the adequacy and scientific sanction of these methods and in the second to set forth and to elucidate the merits and main points and principles of the biological system of sewage purification while offering some practical conclusions and suggestions on the subject generally The pamphlet, which is an elaborately drawn up and well reasoned production, is a reprint from Part XII of the Scientific Memoirs by medical officers of the army of India and it consists of 158 pages together with an appendix and illustrative plans It deserves to be read as a whole, for it does not lend itself to any brief summary Major Roberts starts by referring to a subject about which the readers of THE LANCET need not be reminded—namely, the scourge which enteric fever has proved to our troops serving in India despite all that has been done to prevent or limit its spread There has been of late a growing belief that the dry-earth and trench system of conservancy carried out in hot climates has a good deal to answer for in this respect The dry earth sewage system only deals with latrine matters and does not remove, like a water carriage system, all the sewage products of a population or community However efficiently worked it simply reduces or abolishes nuisance, but it does not reach the causes of disease, on the contrary, as carried out in India and South Africa, for example, by the latrine matters fouling the surface soil and possibly the subsoil water and by getting blown about as dust by the wind or carried in dust storms or by flies it possibly disseminates them

Major Roberts, while recognising that this may not be inappropriately designated nature's method where it is carried out with the most scrupulous regard to all the essential conditions, very forcibly points out how this is not, and practically speaking cannot be, done, at any rate as far as India is concerned, where special difficulties exist and special risks and dangers are incurred, so that it amounts to this—that, to say nothing of the great difficulty of conveyance to the trench and the chances of leakage at every stage, he condemns the present system of latrines and earth disposal as really no system, because it has demonstrably failed in the essential points which it has to fulfil The remedy for all this, in Major Roberts's opinion, is the biological method, the aim and object of which is to recognise the respective parts played by bacterial organisms, to claim and utilise them as allies, and to appropriate them to their special work by adjusting the conditions for securing their rapid multiplication and working efficiency in such order and sequence as to be best fitted for obtaining their efficient coöperation in sewage purification There are various methods of doing this, but they all depend upon one and the same principle. There can be no doubt about the success of the method so far as our present knowledge and experience extend The biological system depends upon water-carriage and water is not always obtainable in hot countries, and, so far as India is concerned, Major Roberts discusses and deals with this point How far it is capable of destroying specific pathogenetic micro organisms has not, perhaps as yet been sufficiently determined experimentally The trend of the experiments undertaken by Dr Houston for the London County Council shows *a diminution in numbers of pathogenic bacteria* and a weakening of their powers, but direct evidence is yet wanting as to whether they are actually extinguished in the biological processes of sewage treatment *Major Roberts's pamphlet* comes at a very opportune time We cannot now discuss the point as to whether or not the harmful microbes can survive the biological treatment and the attacks of other microbes, but we may say that we concur in thinking it would be well to have recourse also to land irrigation—that is, to run the effluent thus obtained over land (which should be cropped) instead of into a watercourse or nullah, with the view, not only of avoiding the waste of a valuable manuring agent, but in order to make assurance doubly sure Where the biological process for liquefying and nitrifying sewage is thoroughly followed the organisms are found to multiply remarkably in number and in working *efficiency, sludge is got rid of, and the resulting effluent*, from the surplus oxygen stored up in it does not seem prone to undergo secondary putrefaction Major Roberts points out the marked differences in the character and strength of the sewage in India and in England respectively He prefers, on the whole, the Scott Moncreiff plan of open upward cultivation tank for anaerobic liquefaction and solution of the solids His description of the conservancy system and of the methods of sewage disposal as followed and worked in India at the present time brings out the existence of many defects and leakages of detail and shows that a good deal still remains to be done in that country in view of remedying these and in designing and developing a more perfect system *for the future* His pamphlet is written in a scientific tone and is by no means lacking in practical proposals. There are a great many points of detail on which there are differences of opinion about upward or downward action and as to whether the septic tank alone or a series of biological filters should be employed, and there are other matters of a technical sort which will probably turn on local and other conditions and considerations and the results of further experimentations, but Major Roberts has meanwhile, we think, done very good service in calling attention to the subject

---

A Treatise on Medical Jurisprudence By GEORGE VIVIAN POORE, M D, F R C P Lond, Professor of the Principles and Practice of Medicine, University College, London Illustrated London. John Murray 1901 Pp 530 Price 12*s*

THIS *treatise is based on* lectures delivered at University College, London We are informed by the author in his preface that the lectures were taken in shorthand for the *Clinical Journal* at the request of its editor, and for the purposes of the present work considerable additions and emendations have been made and the matter has been divided into chapters As a result the style throughout the book is more colloquial than is usual in such a publication, and is all the more acceptable for that reason, as we are thereby presented more exactly with the thoughts and intentions *of the lecturer* Rarely have we found a text book more charming to read and at the same time displaying such a thorough grasp and knowledge of the subject By means of the free employment of illustrative cases, drawn from the records of the law courts and the author's personal experience, the dry details are endowed with lively interest which is likely to imprint them on the student's memory. We thoroughly endorse this plan.

In the first chapter minute directions are given as to the line of conduct that a medical witness should adopt whilst under examination. A barrister will do his utmost to try to confound a medical man whilst giving evidence, but if the latter has carefully considered the case from every point of view he will be enabled to hold his own against any crafty pitfall prepared by skilful and experienced counsel. Dr. Poore gives excellent advice on this subject, and if the practitioner carefully studies this chapter and applies all the advice and suggestions therein contained he need fear neither examination nor cross-examination. Some medical witnesses, especially the younger ones, are occasionally tempted to take a biased view and to try to appear learned about a thing that they know little or nothing about, when cross-examination is apt to become unpleasant. A practitioner should take to heart the following sentence: "If you are perfectly truthful and simple, and, let me say, think of your own reputation, not only for knowledge, but for honesty and truthfulness, you need not fear any cross-examination." Implicit directions are likewise given with regard to dying declarations. It is strange that so many errors are made in taking such declarations. The laws which govern them are explicit and simple, and yet again and again a prosecution breaks down owing to the neglect of the most elementary precautions. The chapter on the Legal Relations of the Medical Profession, containing remarks on the Medical Acts, the General Medical Council, the privileges of medical men, the relation of doctor to patient, malpraxis, the vaccination laws, &c., will be found highly interesting.

Chapters III., IV., and V. are concerned with the signs of death and the examination of persons found dead, with especial reference to medico-legal investigations. The medical jurist is more concerned with the dead than with the living, and hence these preliminary considerations are of the utmost importance. Dr. Poore has the faculty of expressing facts in a very straightforward and plain manner, and there is no mistaking his aim. In a subject like forensic medicine this is especially advantageous. If a dead body is found and foul play is suspected it is, of course, of primary importance that the time at which death took place should be determined as closely as possible. The cases quoted by Dr. Poore to illustrate his remarks on this subject are well chosen, being always to the point and bringing into prominence the phenomena likely to prove of value in a legal inquiry.

In the section devoted to Toxicology the author has limited himself mainly to the discussion of such poisons as have been actually used for criminal purposes and has wisely abstained, as far as possible, from trenching upon the domains of the physiologist, the pharmacologist, and the medical officer of health. The symptoms, post-mortem appearances, and treatment of the various poisons are clearly described, and the many illustrative cases that are brought forward serve further to impress upon the student's mind the difficulties that may arise in regard to differential diagnosis. The manner, too, in which the tests for the poisons are described is striking and original. The lecturer's words were taken down verbatim as he was performing each test; by this means a much more graphic account is given than is usually found in text-books. In speaking of phosphorus poisoning Dr. Poore naturally draws attention to the difficulty in determining between this condition and acute yellow atrophy of the liver, and he comes to the conclusion that it is not possible to say with absolute certainty which of the two is present in doubtful cases. The chapter on Poisoning by Arsenic is an excellent one and contains most interesting accounts of the principal cases of criminal poisoning which have come before the courts. Some interesting remarks are also to be found in the chapter on Food-poisoning; ptomaines, leukomaines, the growth of fungi, and bacteria in food are all duly considered. The medico-legal aspects of sex, sterility, sexual crimes, pregnancy, delivery, abortion, and infanticide are then dealt with in a manner which places before the student and practitioner all the principal points upon which stress is laid when such matters come before the courts either in civil or criminal cases.

The subject of insanity is dealt with in a rather more exhaustive manner than is usually found in text-books on forensic medicine. By means of an admirable series of photographs the various types of insanity are illustrated. Dr. Poore divides insane cases into four classes—congenital insanity, toxic insanity, insanity due to cerebral disease, and symptomatic insanity. This is an admirable classification for dealing with the matter in a small space. The author then considers the "legal relations of the insane," the precautions to be taken when giving certificates being stated at length. The last chapter is entitled the Plea of Insanity in Courts of Law. Four distinct classes of cases are mentioned in which such a plea may be offered: (1) in criminal cases; (2) for divorce or nullity of marriage; (3) testamentary capacity; and (4) affective insanity. A knowledge of such matters may at any time be of the utmost value to a practitioner who may suddenly be called upon to give evidence where the sanity of a litigant is questioned.

Taking this work as a whole we offer our warm congratulations to Dr. Poore on having written one of the most readable and instructive manuals in medical jurisprudence yet published, and we feel sure that it will meet with the success which it deserves. We may add that a study of it would prove useful, not only to medical practitioners and students, but also to barristers who so frequently have to deal with cases involving medical details.

Die Pellagra. By Dr. VICTOR BABES and Dr. V. SION. Illustrated. (Third section of the twenty-fourth volume of Nothnagel's Special Pathology and Therapeutics.) Vienna: Alfred Hölder. 1901. Pp. 75. Price 3 marks 60 pfennig.

PELLAGRA is a disease of which we have little or no experience in England, since it is practically confined to such countries as Italy, Spain, Roumania, and South America, where maize constitutes a common article of diet among the poorer classes. Dr. Victor Babes, professor of pathological anatomy and bacteriology in the University of Bucharest, has had unique opportunities for the study of this disease and with the assistance of Dr. V. Sion has compiled for Nothnagel's Pathology and Therapeutics the very valuable contribution under review.

Not only have the authors brought their practical experience in the disease to bear upon the subject, but they have also drawn up a very complete bibliography and have incorporated in the text all evidence of importance which can help to elucidate this somewhat obscure disease. Although there appear to be certain authors who still cling to the theory that the disease is one which is due to inadequate diet, Dr. Babes, after critically reviewing all the evidence for and against this view, unreservedly declares in favour of the specific nature of the disease. He believes that pellagra is never caused by eating sound maize, and that it only occurs where the grain has previously been exposed to fermentative processes. The exact nature of the poison has not been determined; apparently it can be liberated by many different varieties of bacteria and other fungi. It is soluble in aqueous and alcoholic extracts, and can produce in animals when experimentally injected symptoms analogous to those seen in patients suffering from pellagra. Animals which have recovered from such injections possess in their blood substances which can confer passive immunity in other animals.

Although Dr. Babes believes that ultimately a sero-therapy will be applicable in cases of pellagra occurring in man, he relies rather on prophylactic measures for the stamping out of the disease Such measures should be adopted by the State and should take the form of active supervision in the production, storage, and distribution of the grain

Perhaps the most interesting portions of this volume are those dealing with the pathology and etiology, but the chapters on the course and symptoms of the disease will be read with considerable interest by many in this country, owing to their similarity to those of other diseases with which we are more familiar as, for instance peripheral neuritis and certain degenerative diseases of the central nervous system

---

Infant Feeding in its Relation to Health and Disease By LOUIS FISCHER M D Illustrated Philadelphia F A Davis Company 1901 Pp 368 Price $1 50

DR LOUIS FISCHER's object in undertaking this work on infant feeding has been to gratify the desire of many of his students for detailed information on the most modern and approved methods in this branch of dietetic With enormous practical experience and with a wide knowledge of the contemporary literature the author was apparently in an excellent position for preparing a handbook of this kind and as a book of reference the result is in no way disappointing From a literary standpoint as well as from the student's point of view it presents many deficiencies, the chief of which is an entire lack *of method in the general and particular arrangement of* the various subjects dealt with in the different chapters The reader wanders from chapter to chapter in a vain attempt to unravel the most complete tangle of disconnected facts it is possible to imagine The pages are full of inaccuracies and show evidence of being hurried through the press Of somewhat questionable advantage considering the avowed object of the book, is the author's impartial method of seeing both sides of every question He seldom commits himself to unqualified approval or disapproval of any of the methods of feeding of which he gives particulars and it is quite impossible to decide which method for general purposes is, in the author's opinion, best suited as a working basis If cow's milk is used as a substitute for breast feeding we are told that the less its "vital properties' are interfered with by physical or chemical manipulation the better will it be for the infant For this reason sterilisation is objectionable and mechanical separation of cream is to be avoided The so called vital elements in milk can be absorbed without any process of digestion—hence one obvious advantage of unboiled milk "Sterilised milk continually fed to the exclusion of raw milk or raw beef-juice will ultimately result in rachitis or scurvy '—a statement which is endorsed in a letter from Dr C Dukes published in our columns recently, which has become the subject of much correspondence Many readers will hardly subscribe to Dr Fischer's suggested method for the treatment of chronic constipation which is as follows ' Inject half a tumbler of ordinary glycerine mixed with one pint of warm water In safe hands if the mother or nurse is intelligent there should not only be no injury but positive good from the continued use And on page 301 many readers will wonder what is meant by the following sentence "Milk teeth remain until a child is a year old when they give place to permanent teeth '

Practitioners who take an intelligent interest in modern methods of infant feeding will find this book of real value as a work of reference but it is no book for inexperienced students or for those who have no previous knowledge of the subject

---

LIBRARY TABLE

Appendicitis its Pathology and Surgery By CHARLES BARRETT LOCKWOOD, F R C S Eng, Assistant Surgeon and Lecturer on Descriptive and Surgical Anatomy in St Bartholomew's Hospital London Macmillan and Co 1901. 8vo Pp 296 Price 10s net —If we were to judge by the increase in the number of works on this subject which have in the last year or two appeared from the press we should be inclined to think that appendicitis had become much more frequent of late The explanation of the larger number of books on this disease is to be found rather in the greater care which is now being devoted to the study of appendicitis A few years ago the operation, which has somewhat laboriously been termed ' appendicectomy ' was employed by some surgeons at least for almost every case in which the symptoms pointed to disease of this organ At the present time, however it is recognised that an operation is not needed in every case or even is not desirable The more extended attention which the disease has received has enabled us to discriminate fairly successfully between those cases in which an immediate operation is imperative and those in which an operation would be not merely useless but harmful The time of the operation is also a point of the greatest importance The results of this increase of knowledge are evidenced by a manifest diminution in the death rate and we may look forward to a further improvement in this respect The work before us deals with all the aspects of the disease and its treatment, and it is based on the records of 83 cases in which histological examinations have been made Notes of all these cases are given and they serve to illustrate the chief features of the disease A useful account of the normal anatomy and histology of the appendix will enable normal variations to be distinguished from morbid changes The book is interesting and will well repay perusal

Saunders's Year-book of Medicine and Surgery being a Yearly Digest of Scientific Progress and Authoritative Opinion in all Branches of Medicine and Surgery Collected and arranged under the general editorial charge of GEORGE M GOULD, M D In two vols Surgery London and Philadelphia W B Saunders and Co 1901 —The year book issued under the editorship of Dr George M Gould has for the last five years occupied so well recognised a position among such works that a hearty welcome for this year's issue is assured to it before its appearance We find the same characteristic features which were so well marked in the earlier issues Each branch of the subject has been entrusted to a writer who would be recognised everywhere as an authority in that department Each sub-editor has epitomised the articles and papers which have appeared during 1900 and has in addition expressed his opinion on the value of the new operation or method described We would draw the attention of our readers to the great value of these editorial comments they add enormously to the interest of the work and serve to indicate those novelties which are indeed advances in our knowledge The careful supervision of the general editor is visible everywhere but it is nowhere more conspicuous than in the provision of a very complete index which occupies 48 pages in double columns

The Students' Manual of Venereal Diseases By F J STURGIS M D some time Clinical Professor of Venereal Diseases in the Medical Department of the University of the City of New York. Seventh edition revised and in part rewritten by F R STURGIS, M D, and FOLLEN CABOT, M D Instructor in Genito-Urinary and Venereal Diseases in the Cornell University Medical College, Genito-Urinary Surgeon to Bellevue Hospital Out patients' Department London Rebman Limited 8vo 1901 Pp 216 Price 6s net —The importance to those in general practice of a good knowledge of those diseases which are classed as venereal can hardly be over estimated yet the number of trustworthy handbooks on the subject is small 21 years have passed since Sturgis's Manual of the Venereal Diseases was first issued and it soon achieved as it deserved an extensive circulation in the United States. It is much less widely known in this country and therefore we take pleasure in commending to the attention of medical students this very practical treatise. For the articles on Chancroid and Syphilis Dr. Sturgis is responsible, while the chapters on Gonorrhœa were undertaken by Dr. Cabot. The work is well abreast of the times and the treatment advocated seems always to be judicious. The only criticism we would venture to make is that the account of the hypodermic medication in syphilis is unnecessarily brief, though we must agree with the author that the method is but little used in private practice.

Eczema, with an Analysis of 8000 Cases of the Disease. By L. DUNCAN BULKLEY, A.M., M.D., Physician to the New York Skin and Cancer Hospital, Dermatologist to the Randall's Island Hospitals, Consulting Physician to the New York Hospital, &c. Third edition, entirely rewritten. New York and London: G. P. Putnam's Sons. 1901.—This is the second of a series of works on Dermatology which Dr. Bulkley is bringing out, and eight more are promised. It is called the third edition of the author's work on Eczema and its Management, but the book has been entirely re-written, so that but little remains of the original work. There is no more difficult skin lesion to treat than eczema, and this little volume will afford great aid to the youthful practitioner in dealing with this troublesome disorder. The greater part of the volume is made up of an account of the methods of treatment of the varied manifestations of the disease, and this account is trustworthy; and though there may be room for discussion on some of the points referred to there can be no doubt that the treatment is well described. A valuable list of 72 prescriptions is appended, though its length may serve to confuse the neophyte somewhat, as he may easily be at loss to know which remedy to choose among so many.

Photographic Atlas of the Diseases of the Skin. A series of 80 plates, comprising more than 100 Illustrations, with Descriptive Text and a Treatise on Cutaneous Therapeutics. By GEORGE HENRY FOX, A.M., M.D., Clinical Professor of Diseases of the Skin, College of Physicians and Surgeons, New York, Consulting Dermatologist to the Board of Health, New York City, &c. To be completed in 16 monthly parts. Parts 1, 2, and 3. Philadelphia and London: J. B. Lippincott Company. 1900 and 1901. Price 6*s.* each part, net.—Dr. George Henry Fox is well known on both sides of the Atlantic as a very successful photographer of skin lesions, and already he has issued several works illustrated by this method. Photography has its limitations when employed to represent skin diseases, as the reds and yellows generally come out nearly black. With some precautions these difficulties can be in part obviated, and Dr. Fox's results show how satisfactory the results can be. The reproduced photographs are coloured and give in most cases a very good idea of the disease. Each part contains five plates with descriptions, and also some pages of a very good account of the treatment of diseases of the skin. If all the succeeding parts are as good as those before us the atlas will be a valuable work.

Die Blennorrhöe der Sexualorgane und ihre Complicationen, nachdem neuesten Wissenschaftlichen Standpunkte und zahlreichen eigenen Studien und Untersuchungen. (*Gonorrhœa and its Complications.*) By Dr. ERNEST FINGER. With 36 Woodcuts in the Text and 10 Lithographic Plates. Fifth edition, much enlarged and revised. Leipsic and Vienna: Franz Deutiche. 1901. Pp. 434. Price 7m. 50.—This work by Dr. Finger is well known in this country. It has reached a fifth edition in 12 years and translations of earlier editions have appeared in English, French, Italian, and Russian. This issue has been extremely altered and enlarged and contains a very complete exposition of the present state of our knowledge of the pathology and treatment of gonorrhœa. This disease is looked upon by the public as the least important of all venereal affections. Our increasing knowledge makes it evident that gonorrhœa, though of slight severity and brief in duration, is not uncommonly productive of the most serious res[illegible], and rivals syphilis itself in the number and variety of its manifestations and complications. This is true of the disease both in women and in men; in fact, it is probable that the results are even more important and more far-reaching in the female than in the male. Apart from the avoidance of the chance of infection there is no measure of more importance than an early thorough treatment of the disease, and in order to be able to take the full advantage of the recent advances in treatment medical practitioners should make themselves fully acquainted with the latest therapeutic methods, and no safer guide can be found than this work of Dr. Finger.

Obstetric and Gynecologic Nursing. By EDWARD P. DAVIS, M.D. London and Philadelphia: W. B. Saunders and Co. Illustrated. 8vo. Pp. 402. 1901. Price 8*s.* net.—This book has been written for the training schools of the Jefferson and Philadelphia hospitals. It is divided into two parts, Obstetric and Gynæcologic Nursing. The subject is considered in great detail and the practice of antisepsis and asepsis is strongly insisted upon. The author has been very successful in limiting his information to the amount really required by nurses, and yet has omitted no essential detail. Professor Davis has followed the plan of taking nothing for granted, and therefore, even at the risk of repetition, he has not failed to insist again and again upon important points. In the nursing of midwifery cases the standard aimed at is that attained in most lying-in hospitals, and although we are inclined to think that in the case of the ordinary, cleanly middle-class patient such a standard is an unnecessarily high one, yet it is a good fault to insist upon too much rather than upon too little. Not only nurses, but even newly-qualified medical men, would learn a great deal and would acquire a good idea of what antiseptic and aseptic nursing really means by a perusal of this book. It is written in a clear and pleasant style and is a work which we can recommend. The illustrations are fair and the index is full and complete.

Transactions of the American Gynecological Society. Vol. XXV. For the year 1900. Philadelphia: Doneter. Pp. 470.—The twenty-fifth volume of the Transactions of the American Gynecological Society contains abundant evidence of the vitality of the society. Amongst the more important papers included in the volume are Dr. Engelmann's presidential address upon the American Girl of To-day; an Historical and Experimental Research upon the Anastomoses of the Ureter with the Intestine, by Dr. Peterson; the Evolution of My Technique in the Treatment of Fibroid Uterine Tumour, by Professor Howard Kelly; and an interesting paper upon the Relative Value of Vaginal and Abdominal Operations in the Extirpation of the Pelvic Organs, by Professor Richelot. The proceedings of the twenty-fifth anniversary at Marshall Hall are also given, and include addresses by Dr. Emmet, Dr. Skene, and Dr. Van de Warker.

The Penalty of Death: or, the Problem of Capital Punishment. By JOSIAH OLDFIELD, M.A. Oxon., M.R.C.S. Eng., L.R.C.P. Lond. London: George Bell and Sons. 1901. Pp. 268. Price 3*s.* 6*d.*—Mr. Oldfield has written an interesting work. He objects to the death penalty as being neither necessary nor just, and he had an ally in the person of the late Lord Chief Justice who, in answer to a letter which Mr. Oldfield wrote to him in common with other judges, said that he was opposed to capital punishment It is not very clear what Mr Oldfield considers to be the best way of treating murderers, but apparently he would consent to life long imprisonment with the death penalty to follow if the prisoner killed a warder He quotes, presumably with approval, an opinion of Miss Skene, a lady who has devoted much time to the subject, that flogging joined to penal servitude would have a more deterrent effect than hanging We have always argued that flogging is dreaded by the criminal classes and have recommended it for Hooligans who assault harmless passers-by and for the scoundrels who poison their neighbours by selling putrid meat and adulterated food, but if we remember aright we were met with a chorus of indignation from Mr Joseph Collinson and other humanitarians to the effect that flogging brutalised both him who administered it and the person who received the flogging Mr Oldfield also argues (p 177) that if we wish to prevent a murderer from again committing a murder it is not necessary to hang him, but that under an anæsthetic the chief nerves of his arms and legs could be severed and that in addition portions of his brain could be destroyed so that he would be rendered blind, deaf, dumb, and imbecile He could then be handed over to the spiritual arm to save his soul We do not suppose that Mr Oldfield intends this argument as anything but a *reductio ad absurdum*, and as for the plea that the death penalty is irrevocable it is surely just as irrevocable to convert a man into a helpless imbecile paralytic The hideous farce of solemnly pronouncing a death sentence in such cases as infanticide by young mothers which everybody, including the judge, knows perfectly well will never be carried out should most certainly be put a stop to

JOURNALS AND MAGAZINES

The Quarterly Journal of Microscopical Science Edited by E RAY LANKESTER, M A, LL D, F R S, with the coöperation of ADAM SEDGWICK M A, F R S, W F R WELDON, M A, F R S, and SYDNEY J HICKSON, M A, F R S With Lithographic Plates and Engravings on Wood London J & A Churchill New series, No 175, Vol XLIV Pt 3 May, 1901 Price 10s —The first article in this number is by Gilman A Drew, professor of biology in the University of Maine, Orono, Me, upon the Life History of Nucula Delphinodonta (Mighels) This is a minute mollusc belonging to the Arcidæ, a family of the unionidæ of the order asiphoniata It is only about, four millimetres in length and as it lives below low tide mark it is not very well known to collectors These molluscs live well in aquaria The development of this animal is carefully described from the first division of the ovum and the thrusting forth of the polar bodies to the adult stage The illustrations are numerous and they enable the text to be easily followed. The second article is by W G Ridewood, D Sc., F L S, lecturer on biology at the medical school of St Mary's Hospital, London on the Structure of the Hairs of Mylodon Listai and other South African Edentata The hairs of the great ground sloth have no definite medulla, agreeing in this respect with cholæpus They are destitute of the extra-cortical layer which characterises the hairs of bradypus and have not the fluted surface of the hairs of cholæpus A plate contains figures showing the structure of the hairs The third article is by Edwin S Goodrich, M A, Fellow of Merton College, Oxford, and is on the Structure and Affinities of Saccocirrus, with three plates Saccocirrus is a polychæte worm The fourth article is by George H F Nuttall, M A, M D, University lecturer in bacteriology and preventive medicine, Cambridge, on the question of Priority with regard to Certain Discoveries upon the Ætiology of Malarial Diseases The fifth article is by H M Bernard, M A Cantab, on the Rods and Cones in the Frog and in some other Amphibia, with a plate showing the structure of their parts The last article is by Sydney J Hickson, F R S, Beyer professor of biology in the Owens College, Manchester, and is on Staining with Brazilin

Analytical Records

FROM

THE LANCET LABORATORY.

(1) ELIXIR BROMYL, AND (2) MERCURAMINE

(SQUIRE AND SONS, 413 OXFORD-STREET, LONDON W)

ELIXIR BROMYL is a red syrupy fluid with aromatic taste containing bromine in organic combination The bromine is readily set free on adding nitric acid to the preparation Each fluid drachm contains 10 grains of the organic bromide hexamethylenetetramine-bromethylate, which is obtained by adding ethyl bromide to an alcoholic solution of hexamethylenetetramine, this base being the product of formol acting upon ammonia The dose of the salt is exactly the same as that of the metallic bromides It is being used as a sedative and in epilepsy It is said that this organic compound of bromine possesses all the therapeutic properties of the metallic bromides while secondary effects are not induced, nor does bromism ' result from its administration Mercuramine is a solution of an interesting organic compound of mercury and presents the same germicidal power as a 1 in 50 solution of mercuric chloride It does not, however, coagulate albumin and has thus a decidedly increased penetrative action It is particularly suitable for disinfecting the hands as it does not produce the irritating effect on the skin of corrosive sublimate It is a clear, colourless fluid with an alkaline reaction Hydrochloric acid gave a white crystalline precipitate soluble on heating Potassium iodide gave a yellow precipitate which on heating turned into a light yellow oil The salt is described as the ethylenediamine citrate of mercury Both preparations serve to exemplify the advantages of combining well known drugs like bromine and mercury with an organic rather than an inorganic molecule Organic iodine and silver compounds, again, are further examples of the value of a similar association

DIAZYME ESSENCE

(FAIRCHILD BROTHERS AND FOSTER NEW YORK AND LONDON)

According to our experiments diazyme is a dilute alcoholic solution of the starch converting enzyme combined with aromatics It is quite pleasant to take and has a powerful digestive action It is a clear limpid fluid of a light sherry colour In spite of the presence of alcohol the enzyme present proved to have a rapid digestive action upon starch jelly The preparation is both a digestive and stimulant

NUTRINE BREAD

(NICHOLAS HUTTER AND SON 74, GOLDHAWK ROAD, SHEPHERD'S BUSH, LONDON, W)

This was a brown loaf free from irritating particles. It was of satisfactory uniform texture with good nutty flavour The bread keeps well and moist for a considerable time A mixture of wheats is selected, the choice being calculated to make the bread highly nutritious and digestible Our analysis gave the following results moisture, 47 80 per cent, total proteids, 6 30 per cent, starch, &c, 44 56 per cent, and mineral matter, 1·34 per cent. Not the least important feature in this analysis is the excellent proportion of the normal mineral salts of cereals Bread is too often lacking in regard to these mineral ingredients in which the phosphates predominate. It is important that there should be mineral as well as purely organic food in bread.

TABLOIDS OF ERGOTIN AND STRYCHNINE.

(BURROUGHS, WELLCOME, AND CO., SNOW-HILL-BUILDINGS, LONDON, E.C.)

This combination in the tabloid form is of obvious value, especially having regard to the fact that the drugs selected are of exceptional purity. Each tabloid contains three grains of extract of ergot (ergotin), B.P., associated with one-thirtieth of a grain of sulphate of strychnine.

PIMELUM OINTMENT BASIS.

(BRADY AND MARTIN, NORTHUMBERLAND-ROAD, NEWCASTLE-ON-TYNE.)

Pimelum is a new and excellent basis for ointments. It is of satisfactory consistence, is spread readily, and is an undoubted aid to absorption and penetration. According to our examination it is free from fatty acids and it therefore cannot become rancid. We failed to saponify the basis, so that we may conclude that it is a so-called mineral fat. A great number of ointments of the B.P. strength are made with pimelum base. To mention a few there are pimelum with boric acid, with resorcin and sulphur, with ichthyol, and lastly pimelum with Lassar's paste (for eczema)—a mixture of zinc oxide starch and salicylic acid. The last is known as pimelum amyli compositas and is prepared in two colours, white or pink. Pimelum is an excellent excipient which will keep indefinitely, physically and chemically, under all variations of climate. By itself pimelum is a soothing and emollient unguent.

ALBARGIN.

(MEISTER LUCIUS AND BRUNING, LIMITED, 51, ST. MARY AXE, LONDON, E C.)

Proteid silver compounds have been largely employed of late with advantage in diseases of the urethral canal in place of the ordinary silver salts It is claimed that albargin, the newest member of the proteid silver series, is a distinct improvement on previous silver albumin compounds. Albargin is a compound of silver nitrate with gelatose containing 15 per cent of the metal. It is stated to be free from the irritating tendency of other preparations, though it contains, as will be seen, a much larger proportion of silver than other organic compounds, and accordingly less concentrated and more easily flowing solutions may be employed. Flowing readily, it easily penetrates all parts of the urethral tract. It is easily diffusible According to our examination albargin is a light brown sparkling powder, very soluble in water, giving a neutral solution ; the proteid and the silver could be readily separated. The proteid molecule in albargin is said to be less complex than is the case in other silver albumin preparations. Gelatose, which is combined with the silver in this interesting preparation, is a product of dissociation of gelatin.

ROYAL V.O.V. SCOTCH WHISKY.

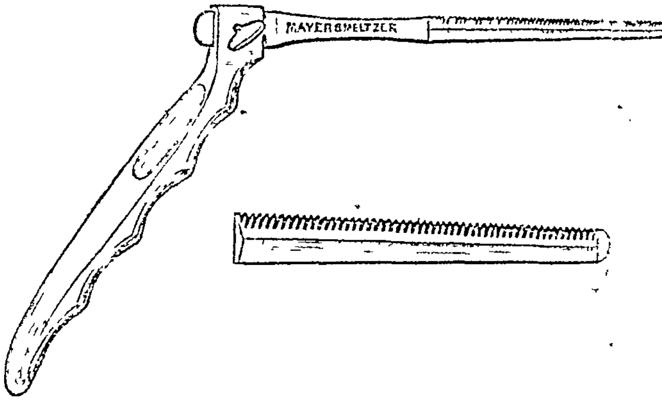
(MACFARLANE AND CO., LADY-LANE, PAISLEY.)

The results of analysis of this spirit were as follows: extractives, 0·20 per cent ; mineral matter. *nil;* acidity reckoned as acetic acid, 0·03 per cent. ; absolute alcohol by weight 39·80 per cent , by volume 47·13 per cent , equal to proof spirit 82·59 per cent. We could find no trace of crude products in the whisky and the test for aldehyde, which includes, of course, furfural, was attended with negative results. All this is in favour of the statement that the whisky is 10 years old It possesses practically no acidity, and having regard to its age the low amount of extractives is remarkable. It is a very pure spirit, somewhat marked in colour, with a good though mild malt flavour.

New Inventions.

A NEW NASAL SAW.

THOSE who have occasion to remove septal irregularities with a saw must be frequently annoyed by the slipping, jamming, or bending of the instrument. To obviate this nasal saws in general use have been made of thicker steel, but in so doing the cutting qualities of the instrument have been markedly impaired. To overcome these difficulties I have had a saw made for me the handle of which fits well to the palm of the hand, and owing to the fact that the handle forms with the blade almost a right angle an uninterrupted view of the operation is permitted. The blades are made with a bevelled edge, so that no matter what the thickness of the blade may be the cutting edge is quite sharp. Two blades are supplied which fit into the same handle. They are applied with the plane surface next the septum ; the one used to cut downward on the right side may by being reversed be used to cut up on the left, and *vice versâ.* The instrument has been thoroughly tried by the staff of the Central London Throat and Ear Hospital and has given every satisfaction Messrs. Meyer and Meltzer of Great Portland-street, W., are the makers.



PERRY G. GOLDSMITH, M.D., C.M. Toronto,
Registrar, Central London Throat and Ear Hospital

DURHAM UNIVERSITY MEDICAL GRADUATES' ASSOCIATION.

THE annual meeting of this association was held at the rooms of the Medical Society of London on June 27th, when the following officers were appointed for the year 1901–1902 :—President : Dr. Frederick S. Palmer. Vice-Presidents : Dr W. D. Arnison and Dr. Frederick Spicer. Members of the Council : Dr. Mitchell Bird, Dr. Charles Blair, Dr. Percy Jakins, Dr. T. Beattie, Dr. R. A. Bolam, Dr. E. W. Diver, Dr. J. W. Hembrough, Dr. Charles W. Chapman, Dr. W. G Richardson, Dr. John Eyre, Dr. J. T. James, and Dr. A. Cox. Honorary treasurer : Dr. Selby W. Plummer. Honorary secretaries : Dr. H. Brunton Angus and Dr. T. Outterson Wood.

In the evening the members and guests to the number of 77 dined together at the Café Royal, Dr. Frederick S. Palmer, the President of the association, being in the chair. After the usual patriotic toasts had been proposed by the President he gave the toast of "The University of Durham," and Dr. Selby Plummer, a member of the Senate of the University, replied. Sir James Crichton Browne proposed in eloquent terms "Success to the University of Durham Medical Graduates' Association," recalling his connexion with the medical college where he was formerly lecturer on mental diseases, and Dr. H. Brunton Angus, the northern secretary, replied, congratulating the association upon its success, the number of members now reaching close upon 400. "The Health of the President" was proposed by Mr. Christopher Heath, "The Health of the Visitors" by Dr. Frederick Spicer, Sir R Douglas Powell, Bart., K.C.V.O., replying, and the President proposed "The Health of the Honorary Secretary for the South" (Dr. T. Outterson Wood) Excellent music was given under the direction of Mr. Arthur E. Godfrey, and a most enjoyable and successful evening was spent.

THE LANCET.

LONDON SATURDAY, JULY 6, 1901

The Army Medical Service.

IN our issue of last week we observed in reference to the anticipated inquiry into the subject of the reorganisation of the Army Medical Service that the sooner this inquiry was undertaken the better for all concerned and that the promulgation of the names of those who were to constitute the committee was anxiously anticipated. By one of those *coincidences which not uncommonly happen in the ordinary* course of affairs the Secretary of State for War was at about the time that we went to press announcing from his place in Parliament the composition of the committee in question

We can do little more now than give the impressions conveyed to our minds by a perusal of Mr BRODRICK'S statement and, pending further information, make such few comments as occur to us at the moment Mr BRODRICK said that he had received a number of suggestions and representations from various quarters and that a committee of experts had been appointed to consider a scheme which he (Mr BRODRICK) had drawn up for the future organisation of the Army Medical Service From this it would appear that it is not intended to frame any scheme upon the lines of the suggestions and recommendations of the committee after it has duly investigated and considered the subject, but that a scheme of proposals will be at once submitted for their consideration and report It may be that this plan of procedure has been adopted on business principles and with the practical end in view of giving a definite aim to the committee's proceedings We have no particular fault to find with Mr BRODRICK'S deprecation of hurry in the performance of the task assigned to the committee, on the contrary, we quite agree with him that where the object is to put the Army Medical Service on a permanently good footing the more thoroughly and carefully the matter is considered the better

The committee will consist of the following members —Mr *HOWARD H* TOOTH, *C M G M D* Cantab, F R C P Lond, St Bartholomew's Hospital, Mr GEORGE H MAKINS C B F R C S Eng, St Thomas's Hospital, Mr ALFRED D FRIPP C B, F R C S Eng, Guy's Hospital, Sir F TREVES K C V O C B, F R C S Eng, London Hospital, Mr ALEXANDER OGSTON, M D Aberd, Scotland, Lieutenant Colonel A. H KEOGH R.A M C, C B, M D R U I, Ireland, Mr E C PERRY, M D Cantab, F R C P Lond, Senate of London University Surgeon General W R HOOPER I M S, C S I President of the Medical Board, India Office, and two officers who will be named by the Commander in Chief to represent the Army The secretary will be Major H E R. JAMES, R A M C, F R C S Eng Mr BRODRICK in announcing the names of the members of the committee added that he proposed to take the chair himself If this is to be regarded as an indication of the importance which the Government attach to the inquiry and, as we hope and believe as an earnest of the desire on Mr BRODRICK'S part to carry out the inquiry to a successful conclusion the medical service and the profession generally are to be congratulated We have no desire to approach or *to deal with the matter in any spirit of fault finding* or carping criticism but we feel bound to remark that the constitution of the committee is unsatisfactory in one very important respect The name of an army medical officer of high administrative rank and experience, with a knowledge of military organisation and the requirements of field medical service is conspicuous by its absence We think that this omission is much to be regretted and that it should be remedied It is accentuated rather than otherwise by the fact that two purely military officers it is presumed and not military medical officers *are to be named by the Commander in Chief to represent the* army on the committee We sincerely trust that the committee will be empowered to call any witnesses whom they may desire to examine

There can be no doubt that the names of the civil medical members of the committee are those of men of high scientific attainments and standing in their profession who are well acquainted with the requirements of the medical and surgical sides of civil hospital work. We may assume that the great and pressing object which the Government has in view at the present time is to ascertain what inducements are needed to make the army an attractive career to medical men and to supply the ranks of a medical service which is fast emptying itself with a class of men of a high average standard of medical qualifications together with a good sprinkling of men possessing the best professional attainments The names of the members of the profession in civil life appointed to serve on the committee are a sufficient guarantee that the requisite information on these points will be forthcoming

Dr. Metchnikoff on the Flora of the Human Body.

WE are now paying the penalty for the advantage which our ancestors enjoyed in the possession of long intestines inhabited by a rich microbic flora This, stated briefly, was the text of Dr ÉLIE METCHNIKOFF'S Wilde Lecture which was delivered before the Manchester Literary and Philosophical Society and which has recently been published in its memoirs and proceedings It is the more interesting that *doubts* should now be thrown on the utility of the bacterial flora of the present human intestine, because it is only recently that other workers in the same field of science have adduced fragments of evidence which suggest that in many unsuspected instances these humble organisms fulfil a distinctly useful role in this and other departments of the animal economy For instance, our long cherished belief that the bacterial flora of the buccal cavity is only operative for harm receives a rude shock in the recent pronouncement that the presence of micro organisms is essential to evoke in the salivary secretions that ptyalising function which heretofore they were supposed to possess in their own right Isolated instances of this kind—and there are many of them—do not in any way militate against the lecturer's fundamental contention that as far as man is concerned *in his present stage of evolution* not only are the bacterial inhabitants of the intestine a distinct disadvantage to him, but, further, that the large intestine itself, the cæcum, and the vermiform appendix are morphological anachronisms, and directly responsible for certain pathological consequences which curtail life and may compass its end.

During the earlier and simpler stages of our ancestral history the possession of a voluminous intestine was no doubt necessitated by the nature of the food and was the expression of a responsive adaptation to the requirements of the environment. For the same reason saprophytic parasites were welcomed in the organism for the disintegration of cellulose. The advance of civilisation and the evolution of intellect and brain have entirely altered the conditions. For instance, the culinary art and the principles of modern gastronomics have modified the use of teeth for the attrition of food, and, further, the stomach and large portions of the intestine can be removed by the surgeon without apparent detriment to the physiological processes of digestion and absorption. Taking these facts into consideration, perhaps Dr. METCHNIKOFF is justified in hazarding the suggestion that the large intestine, the cæcum, and the appendix are in process of slow involution. Although, unfortunately, we possess no morphological evidence in proof of this contention, there is no reason to suppose that the developmental behaviour of these structures should disobey the fundamental biological law that functionless organs tend to disappear. Comparative pathology teaches us that organs in process of involution are specially vulnerable to disease and readily become the seat of parasitic invasion, and it is suggestive, to say the least, that cancer of the rectum and appendicitis are to all appearances greatly on the increase. The slow operation of natural causes to bring about the atrophy of useless organs in civilised man can hardly be accelerated by surgical interference or medical skill. The removal of the prepuce among Semitic people for hundreds of generations has not by one millimetre shortened the length of this apparently useless appendage. Nay, rather by interfering with the operation of natural selection and the elimination of those in whom the prepuce has tended to assume proportions actually dangerous to health, the practice of circumcision must have operated in the reverse direction.

Dr. METCHNIKOFF is of the opinion that medicine will ultimately cope more successfully with noxious microbes and their effects, and that the progress of surgery will enable us to remove by operation parts or organs propitious to the growth of a microbic flora. The consummation of this desirable end will be of the greatest advantage to the individual, but for the reasons previously stated it will tend to perpetuate in the race undesirable characteristics and functionless organs. The incubation of micro-organisms within the large intestine inevitably leads to the absorption into the system of considerable quantities of toxic substances, fatty acids, aromatic bodies, and other products of putrefaction. These, according to Dr. METCHNIKOFF, are the exciting causes, direct and indirect, of fibrosis, the so-called functional neuroses, and early decay. The toxic character of the urine in such cases is due to the elimination by the kidneys of the noxious bodies generated in other areas of the body, such as the bowel and skin; but the pathological consequences of parasitic invasion are not confined to the absorption of poisons, for it occasionally happens that the micro-organisms actually make their way into the living tissues and disintegrate the still vital material of which they are composed. As the tissues become gradually devitalised by the toxic action of absorbed poison the task of the bacterial flora becomes progressively easier—indeed, as HUEPPE has strenuously contended, this gradual training of purely saprophytic function may be a stage in the evolution of advanced parasitism. It is impossible to read the Wilde Lecture for 1901 without being struck by many of the suggestive theories which Dr. METCHNIKOFF put before his audience at Manchester, but we take it that the time is not yet ripe for the acceptance by the majority of medical men of many of his advanced biological tenets.

An Examination of the Abbé Diffraction Theory of the Microscope.

A VERY interesting paper on the above subject was read by Mr. J. W. GORDON at a meeting of the Royal Microscopical Society on June 19th. The Abbé theory has been so widely accepted and the experimental inquiries which have been made to test it have been in such complete harmony with it that most microscopists have thought that its truth scarcely admits of a doubt. But the accepted theories of to-day become the fallacies of to-morrow as knowledge accumulates and fresh light is thrown upon a subject. Mr. GORDON showed in his paper, not only that there are many facts which are inconsistent with the Abbé theory, but that the main facts which were supposed to demonstrate the theory may be explained in an entirely different manner. The Abbé theory, briefly stated, is that there is a wide difference between macroscopic and microscopic vision. In vision with the naked eye or with a lens free from spherical or chromatic aberration we obtain geometrically correct pictures produced in accordance with the laws of refraction. These dioptric images truly represent the appearance which the objects themselves would present were they enlarged to the same scale and viewed under similar illumination. We are therefore justified in drawing the same conclusions with regard to the structure of the objects which they picture as we should draw from the direct vision of actual objects having the same dimensions. This is not the case in the microscopic vision of minute objects and ABBÉ assumed that the images of minute objects are not delineated microscopically by means of the ordinary laws of refraction; they are not dioptrical results, but depend entirely on the laws of diffraction. HELMHOLTZ and ABBÉ concluded that no amount of magnifying power can separate dioptrically two lines, markings, or apertures of any kind, not more than $\frac{1}{2500}$th of an inch apart. ABBÉ assumed that the visual separation of more closely approximated lines or other markings is entirely the result of diffraction, the objective receiving and transmitting not only the ordinary dioptric rays but the inflected rays the course of which has been altered on their way through the object by some peculiarity in the disposition of its particles. These rays when acted upon by the objective produce diffraction spectra. If the markings are so closely approximated as to produce a wide dispersion of the interference spectra only a part of them may fall within the range of the objective and the re-combination of these may produce a diffraction image differing more or less completely from the real structure. Mr. GORDON first dealt with the theory on theoretical grounds and summarised his results as follows: "The calculation upon which the theory rests is itself based upon two fundamental errors—one as to the position of the real diffraction images in the principal focal plane of the microscope, the other as to the phase relation between the direct and the diffracted rays. The theory itself, when extended to determine the number of bright lines seen in the real image of a diffraction grating, their position in the picture, and their individual appearance, breaks down entirely and yields only conclusions which are wholly at variance with the facts."

He next dealt with the phenomena which most writers have regarded as sufficient proof of the accuracy of ABBÉ'S conclusions. For the purpose of demonstrating the Abbé theory a grating ruled alternately with long and short lines is employed, the lines being traced with a diamond point on a film of silver of extreme tenuity deposited on a thin glass cover. It is easy to demonstrate that these lines form diffraction spectra, but the experiments of ABBÉ are employed to show the change *which may take place in the appearance of an object* by shutting off a certain number of the diffraction spectra. This is accomplished by using diaphragms with one or more slits placed immediately behind the objective, so that certain diffraction spectra are allowed to pass and others are excluded. Mr. GORDON contended that the pattern of the image formed in the microscope of the diffraction plate does not in any way depend upon the particular diffraction spectra which contribute rays to its formation and that the features of this image are affected by diffraction arising in the diaphragms themselves. In support of this view he showed that the Abbé phenomena may be exhibited by objects which are incapable of producing any diffraction spectra at all. For this purpose a self-luminous object was employed. This was obtained with a ruled glass plate with a number of lines traced at a distance of $\frac{1}{100}$th of an inch apart in a film of soot. The lines had the same proportional diameter, one to seven, relatively to their dark interspaces that the lines of the coarser ruling in the Abbé diffraction plate have to their intervening spaces. This glass plate is arranged at a suitable distance behind the substage condenser and its image is focussed upon the stage of the microscope side by side with the ruling on the Abbé diffraction plate. By a little management the aerial image of the carbon film may be made to assume the exact dimensions of the Abbé ruling, so that there are two objects in the field visibly alike but differing in the important particular that the one can and the other cannot be made to yield diffraction spectra. Mr. GORDON showed that all the various experiments which can be made with the Abbé film can be repeated with the two objects simultaneously and that in all cases it will be found that there is no difference between the behaviour of the one and that of the other. When the one is blurred the other is blurred; when the ruling appears doubled in the one it appears doubled in the other; when it appears trebled in the one it appears trebled in the other. Whatever results the diffraction plate can be made to yield this ghostly grating with no diffracted rays to be manipulated contrives to yield also There were very many theoretical considerations which Mr. GORDON has not confirmed by experiment, but it is evident that the subject is one on which a great deal of useful work may be done, especially with the view of improving the resolving power of objectives.

◆

"By Accident."

THE interpretation of the Workmen's Compensation Acts concerns His Majesty's judges rather than ourselves, but medical practitioners have already obviously so much responsibility imposed upon them in connexion with these Acts that we watch jealously any decisions likely to increase that responsibility. The case of PERRY v. BAKER, heard before His Honour Judge STONOR recently, illustrated the effect of sundry decisions of the Court of Appeal to which we need not refer in detail. The man PERRY injured himself in lifting a heavy oak seat that he was making for his employers in order to examine it underneath. The medical evidence for the applicant on this point was, according to the judge's note, that the exertion of lifting the bench strained or otherwise injured the applicant in the muscles of the back and probably otherwise, that he had also received considerable shock, and that his recovery was extremely doubtful. A question was raised as to the state of his health which does not seem to have affected the result. Judge STONOR intimated that to his unaided intelligence, which by the way is that of a judge of over 35 years' standing, this would have seemed an accident which would entitle the applicant to recover compensation. According, however, to decided cases there must be the presence of a fortuitous element to turn a normal condition of affairs into a catastrophe and to cause the injury to constitute an accident, and by the light of the same cases the injury which the man PERRY did to himself was not the result of anything fortuitous or unexpected. In illustration of this we may mention that a man, who had strained himself by over-exertion much as PERRY did, was once held entitled to recover because the planks which he was lifting were frozen together, so that the exertion required was greater than it would otherwise have been, and this, it was thought, imported an unexpected and fortuitous element into his case. We have not space to follow the Lords Justices in the splitting of hairs necessary for the interpretation of one of the worst drafted Acts of Parliament on the statute-book or to criticise the learned county-court judge whom we assume to have decided correctly according to precedent. It seems to us, however, that when the employer was made liable for "injury by accident arising out of, and in the course of, the workman's employment," an apparent limitation was introduced which would have been absent had the words "by accident" been omitted, and to which the interpretations referred to have given an effect that was perhaps not originally intended. The words, for example, may have been merely intended to exclude such "injury" as lead poisoning or illness contracted owing to insanitary conditions. As matters now stand, however, they eliminate injury in the ordinary sense of the term if it occurs in certain ways, and the precise way in which the injury has been received thus becomes frequently the point upon which the case of each party hinges, while the medical witness, who has quite enough responsibility already in forming and enunciating his opinion as to the extent and the probable duration of the injury, is at once liable to be drawn into opinions and discussions as to whether there was an "accident" and how the "accident" took place—a matter on which he can only speculate, though perhaps from a slightly better point of view than other witnesses. He speculates, moreover, knowing that on his opinion may depend the livelihood of a poor man who in any case will be a cripple for life. Can it be wondered at that in such instances "expert evidence" becomes more uncertain and contradictory than it should be, and that it also often becomes the subject of unfavourable remark and undeserved generalities? We have not commented on the case before us from the point of view of justice or common sense. Had we done so we should have pointed out that the Act and decisions taken together seem to put a premium on negligence and to leave zeal and hard work at a discount. The workman who is injured through his own carelessness not amounting to serious and wilful misconduct, or through the carelessness of some fellow-workman whose conduct he regards with natural indifference, is to be compensated. The man who works too hard may injure himself without chance of compensation. At present the best advice that can be given to the working man is that he should not attempt too much, especially in the way of weight-lifting and other violent exertion. It is quite easy for a man to injure himself by doing that which he has already done frequently with apparent impunity, but such injury is not caused by an accident within the meaning of the Act.

Annotations.

"Ne quid nimis."

THE LONDON SCHOOL BOARD AND MEDICAL CERTIFICATES.

That remarkable body, the London School Board, has again been showing its want of common sense. Some little time ago a summons was taken out at the South-Western Police-court against William Stannet by one of its officials for neglecting to send his child to school. The mother of the child produced a certificate from Dr. J. Myles stating that the child was unable to attend school on account of her suffering from valvular disease of the heart. The complainant, in the usual manner of school board officials, objected to this certificate and the magistrate granted an adjournment to allow of the child being examined by Mr. F. C. Kempster on behalf of the board. The certificate given by Mr. Kempster practically agreed with that of Dr. Myles, but also it is reported as having contained the assertion that "the child would be just as well in school as nursing a baby at home." On June 29th Mr. Garrett adjudicated on the case, and the official suggested that the child should be made to attend school under a magistrate's order. Dr. Myles said that he had known the child for 12 months; she had been very seriously ill but was now better. If the mother took his advice she would refuse to send the child to school until after the summer holidays. Mr. Garrett thereupon refused to make an order and administered a rebuke to one of the school board visitors for making an observation about the medical man who had given evidence. The London School Board never seems to learn wisdom. Why could it not be satisfied with Dr. Myles's certificate? This was not a case in which the child was simply stated on medical authority to be unfit to attend school. An explicit diagnosis was given, a diagnosis of one of the most serious diseases to which humanity is liable. Mr. Kempster's diagnosis coincided, and with all due deference to him we take leave to doubt that nursing a baby is as deleterious in a case of heart disease as going to school, unless, indeed, the child walked about the room carrying the baby. But the case is very characteristic of the policy of the School Board as regards medical men. If a medical man is on the side of the board he is worthy of every credit; if not he is never believed. The board had best stick to its last fad of teaching children the violin, which, if extravagant, is not likely to result in death.

A FINE PERFORMANCE.

The endurance and self-sacrifice of medical officers and of stretcher-bearers in South Africa have been the object of much well-deserved praise, and naturally the opportunity for the display of such qualities in the same way does not frequently arise in ordinary civil life. When such an opportunity does arise, however, it is a fine thing that the call should be willingly and promptly answered. Such was conspicuously the case on a recent occasion in Gloucestershire which is narrated to the *Standard* by a correspondent who adds that "we hear of so many brave acts during war that it is well to see that brave and kind ones occur also in peace." All praise is due to the members of the Sharpness ambulance corps, who at a moment's notice went some miles to the help of a man whom a medical practitioner had pronounced to be in need of surgical aid not practicable where he was. They bore the patient, a heavy man, a mile to a steam tug, took him 16 miles on a canal, and then bore him one and a half miles to his destination—a nursing home. They then had an 18-mile journey which landed them home at 3 A.M., and they refused any remuneration for their time and trouble. Such exertions would be admirable even if made in the course of duty, but when the only duty responded to is the general one lying on all men to succour the sick, voluntary efforts of this degree are worthy of the sincerest admiration.

THE HOUSING OF THE POOR AT BATH.

The medical officer of health of the Bath Urban Sanitary Authority has just issued a report on the housing of the working classes in that district. Dr. W. H. Symons therein points out the fallacy of judging overcrowding by general statistics. Thus, the density of population for the 33 largest towns is equal to 33·8 persons per acre, while for the 67 other large towns, including Bath, the average in 1900 was 13·8 per acre. In London the density of population is 59 to the acre, but at Whitechapel it amounts to 208, while at Lewisham it is only 10 per acre. So also at Bath the census of 1901 gives the population as 14·8 per acre, but while it amounts to only 7·4 persons in the parish of Bathwick, it exceeds 77 persons per acre in the central parishes. The real point is to ascertain whether there is at least 300 cubic feet per person in bedrooms and 400 cubic feet in rooms where work is done during the day. Even this is a very low average and every effort should be made to raise it to 500 cubic feet per person. Dr. Symons very appropriately remarks that when the water-supply is accidentally polluted the results are soon apparent. The ratepayers and bread-winners are stricken down and steps are at once taken to stop the pollution. Then he adds: "The effects of polluted air—air contaminated with sewage or waste products from the lungs—are more insidious, less easily noticed but not less fatal." Of those who die between the ages of 15 and 35 years probably more than half would have lived to be much older if they had been able to obtain a sufficient supply of fresh air. In this respect, however, the town of Bath should be exceptionally fortunate. Unlike the great industrial centres, social and economic causes have combined to relieve the pressure on space. Thus in 1851 there were 11,647 persons living in 1349 houses in the centre of the city. Now on precisely the same ground there are only 7577 persons living in 1342 houses. Practically the houses are the same, but their inhabitants have decreased in the proportion of 35 per cent. and there are only a few cases of overcrowding. For the remainder of the city, comprising 1935 houses there has been a decrease in the last 50 years of 346 inhabitants, and taking the city as a whole the population has fallen from 4423 to 4077. On the other hand, the population of the suburban parishes, where there is plenty of room and not the same risk of overcrowding, has increased from 7557 to 20,074. In spite, however, of these most favourable circumstances, according to the Registrar-General's return for 1891 there were 4·11 per cent. of the population of Bath living in overcrowded tenements. It is true that the average of overcrowding for England in town and country was then set down at 11·23 per cent. One of the difficulties at Bath is that much of the lowest class property belongs to landlords who themselves are so very poor that they cannot afford to make the necessary repairs. Also there are certain districts subject to floods. Some improvements have been effected. Model dwellings have been constructed and these were described in our special report on the Sanitary Condition of Bath, which was published in THE LANCET of Oct. 14th, 1899, p. 1061. At the same time we there gave an account of some of the sanitary defects still subsisting. Since then a loan was approved by the Local Government Board (in December, 1899) for £10,500. With this money the level of some of the ground subject to floods has been raised and 16 model tenements have been built thereon. Another scheme by which 189 persons are affected has been sanctioned, but though some of the insanitary houses have been demolished no new structures have as yet been erected. The great difficulty in Bath, as elsewhere, is to re-house the class of tenants who overcrowd insanitary areas. At Bath there are several hundred families who cannot afford to pay more than 2*s.* 6*d.* a week rent, and therefore the model dwellings which are built in the place of the ancient rookeries attract a higher class of tenants. Thus the last census showed that there were at Bath 170 three-roomed tenements each containing six inhabitants, 70 tenements had each seven inhabitants, 53 had eight inhabitants, 23 had nine inhabitants; eight had 10 inhabitants, and two had 11 inhabitants. Then there were 3000 persons living as families of three or more persons in tenements of only one or two rooms. The Local Government Board will not sanction one-room tenements. Dr. Symons himself thinks that three rooms are the least that can be allowed for decent family life; yet it does not seem possible to provide three rooms for 2*s.* 6*d.* per week. Here there is evidently a deadlock and the report before us does not suggest a solution.

A NEW "SPORT"

WE know not how the term "sport" as distinguished from cruelty is to be defined unless it is by reference to that sense of common justice which demands a fair chance for the hunted animal and protects the inoffensive and defenceless. It is in accordance with this feeling that the bull-ring has died out with our ancestors. But the heads of Hydra are not soon disposed of. Petty forms of cruelty arise wherever there exists a morbid spirit of destructiveness unchecked by any love of nature or regard for the lower creation. According to a contemporary a club has been formed in the New Forest and probably others elsewhere, for the purpose of squirrel-shooting. Everyone who delights in the beauty of woodland life and scenery must greatly regret the introduction of a so-called sport which is at once as cruel as it is useless and wanton. The comparative tameness of the squirrel renders it in many cases an easy prey. Its body is of little value to anyone. Its disappearance would remove one of the most beautiful attractions of rural nature. We join with our contemporary in expressing the strongest disapproval of these shooting clubs, and we would call upon local authorities throughout the country to prohibit their formation. If steps are not soon taken to enforce the various Acts available for the protection of wild life, and further to extend that protection, we shall find that many birds and beasts once common in this country will have to be catalogued as "rare" and some probably as "extinct."

AN EXTRAORDINARY CASE OF THE LOSS OF SENSE OF PERSONAL IDENTITY.

ON Wednesday, June 5th, a young lady who had suddenly lost her memory and sense of identity while cycling at Tunbridge Wells a few days before was discovered and restored to her parents at New Cross. Her mind was now a perfect blank and she did not recollect anything, not even her name. In a paper read before the Section of Nervous and Mental Diseases on June 6th, at the annual meeting of the American Medical Association, Dr. Edward E. Mayer of Pittsburg reports the following case illustrative of a similar disorder of mind. A young man born in Pennsylvania in 1860 was riding in a railway train in 1884, when it was wrecked. He felt himself hurled through the air and then lost consciousness and remembered nothing. On regaining consciousness it turned out that he had lost all recollection or knowledge of anything that occurred for a period of five years before the accident, and no one could be found who was able to give any information about him. Twelve years ago, in 1889, he first arrived at Pittsburg and met his present wife, and two years later married her. He was never able to give her any information regarding his previous life, although he had not forgotten his name. In 1892, shortly before the birth of his eldest child, he wandered away one Sunday afternoon and did not return until Monday evening and could not then give any account of his absence. As he was a total abstainer this conduct was regarded as peculiar. About a year later, in 1893, he disappeared for several days, and during his absence he sent a postal card to his wife, telling her that the memory of his mother had suddenly returned to him and that he had gone to pay her a visit. He returned home a day or two later. The man's occupation before he met with the railway accident was that of a carpenter, but after his marriage he was employed at different times as a farmer, sawyer, and painter. About this time he complained of symptoms which led his medical adviser to suspect abscess of the liver. One day in February, 1901, while suffering intensely from abdominal pain, he fell down on the floor and lay unconscious for several hours. When he regained consciousness the memory of the last 17 years of his life (1884–1901) was apparently entirely obliterated. The only consciousness preserved was that of his life previously to the railway accident. He insisted that he was 24 years old (whereas he was 41) and that he had neither wife nor children. The surroundings among which he had lived for the past 12 years were apparently strange to him, and it required much persuasion to induce him to believe the story of the true state of affairs. The symptoms of hepatic abscess now also disappeared. He tried to resume his long-forgotten work as a carpenter, but his hand had lost its cunning and he was obliged to begin as an apprentice. On March 8th last he disappeared for 12 hours and upon his return home he stated that he had walked about 30 miles in the country—his condition presumably being one of sub-conscious automatism, probably of epileptic origin. The following day he went out to buy some groceries but did not return home and no word or trace of him had been received since by his wife. This case, apart from its psychological interest, has many features of resemblance to a case of epilepsy recorded in these columns[1] and possesses considerable medico-legal importance in regard to the responsibility for deeds committed during the condition of mental automatism peculiar to such cases.

TEA INTOXICATION WITH SPINAL SYMPTOMS.

A paper dealing with an obscure and little known group of spinal symptoms arising from the abuse of tea was read by Dr. Alfred Gordon at the June meeting of the Philadelphia Neurological Society. He presented a patient, a woman, aged 31 years, who seven years previously had had an operation performed for some condition of the uterus. Since then she had contracted the habit of drinking tea to excess, sometimes 15 cups a day. Three months previously her present illness began with symptoms of fatigue and unsteadiness in walking. The knee-jerks were increased, sensation was altered, and hyperæsthesia was present in the lower extremities. The pupils were unequal and there was nystagmus. Romberg's symptom was present. Recently she had suffered from "spells of unconsciousness" lasting for a few moments. There was a feeling of weariness in the legs and the clinical picture was that of hysteria and of lateral sclerosis. Cases of this kind, says Dr. Gordon, are rare, and the possibility of contamination of the tea with lead in minute quantities should be borne in mind. In the discussion following the above communication Dr. D. J. McCarthy said that he had seen a case where the patient was accustomed to take as much as 10 cups of tea a day. In that case the symptoms pointed to sclerosis of the spinal cord.

AN ANTI-VACCINATION BILL.

We observe among the private members' Bills that are before the House of Commons one which purports to amend the Vaccination Acts and which exemplifies the tendency of the would-be legislator to follow up any newly made alteration in the law with a proposal that seeks to "go one better," and that in doing so would threaten serious mischief if the introduction of a Bill by a private member were to imply in any considerable number of cases the production of a new Act of Parliament. As illustrations of our meaning we might cite an attempt of the present year to limit the working day of the miner to eight hours from bank to bank—that is, to reckon his time in the mine on his way to his work as well as his time actually working—and other Bills which have sought to forbid the employer, already made responsible for injuries done to a workman by the negligence of his fellows, from setting up in answer to an action for compensation contributory negligence, or wilful misconduct on the part of the injured workman or "any other defence" (*sic*) to an action for compensation. The Bill to which we now call attention follows up the clause in the recent Vaccination Act which brought into being the conscientious objector by seeking to enact that "no parent or person having the custody of a child shall be compelled or ordered to vaccinate such child by any justice, court, or other, having authority hitherto, to so compel or order." The particular portion of the operative section which we have quoted seems a little obscure in its drafting, but its intention is tolerably clear and its defects may be in part due to the excitement of the reformer when confronted with compulsory vaccination. It is a matter of regret to many that want of time or the facilities afforded by the rules and customs of the House of Commons frequently hinder or arrest useful legislation introduced by private members. On other occasions no one can deny that such rules and customs are capable of use as well as of abuse and that the suppression and silent obliteration of Bills may be quite as beneficial as the discussion of them.

BACTERIOLOGY AND THE FOOD AND DRUGS ACT.

There can be little doubt that those who were responsible for the framing of the Food and Drugs Act never intended or even foresaw that its clauses could apply to bacterial contamination and such contamination, be it remarked, is for a bacteriologist rather than a chemist or analyst to discover. The question opens a very wide field of inquiry and action, but already, as we pointed out in a leading article last week, it has been held that milk contaminated with pathogenic bacteria is prejudicial to the purchaser within the meaning of the Food and Drugs Act. We wonder how many public analysts are qualified to detect pathogenic bacteria in milk or other articles of consumption. We imagine but very few, and therefore this ruling sooner or later is bound to have a disturbing influence on the machinery of the Act. We note that the Institute of Chemistry has already established an examination in biological chemistry with special reference to the chemistry and bacteriology of foods, water, sewage, and effluents, and the practical applications of biological chemistry to industries. Our own view is that the public analyst can hardly be expected to undertake the very intricate work of bacteriological investigation, and such, in our opinion, should be referred at his instance to a bacteriologist. But we recognise the desirability of public analysts being made familiar with this work and its details. In the same way it is important, we think, that the public analyst should have a more intimate knowledge of drugs and therapeutics than he has hitherto been shown to possess, and here again the Institute of Chemistry has designed an examination with the view of certifying that he possesses such a knowledge; of course on no grounds should the possession of such a certificate be regarded as in the smallest sense a medical qualification.

THE ASSOCIATION OF PUBLIC VACCINATORS.

The second annual dinner of the Association of Public Vaccinators was held on June 28th, at the Hotel Great Central, Marylebone-road, N.W., at the close of the annual general meeting. A large number of members, including representatives from Lancashire, Gloucestershire, and the eastern counties, assembled under the presidency of Mr. E. Climson Greenwood, president of the association. After dinner some capital musical entertainment was provided in addition to that which arose from the various speeches. Most of the speakers alluded in glowing terms to the excellence of the glycerinated calf-lymph now supplied by the Government, and Dr. S. Monckton Copeman, responding for the Local Government Board, explained that the dissatisfaction which was caused at first was due to the large initial demand, a demand far larger than had been anticipated, as a result of the new Vaccination Act. Mr. R. Macartney utilised the duty which had been entrusted to him of proposing the toast of "The Association of Public Vaccinators" to state very clearly the defects in the status of public vaccinators under the present Act. Dr. A. E. Cope in responding to this toast was able to give a very satisfactory account of the condition and prospects of the association. The "conscientious objector" was naturally the object of many remarks, and some quaint anecdotes were forthcoming which tended to show that it was quite possible to be an objector without being conscientious Inefficient vaccination and the 'one mark' man also figured prominently in the speeches of members of the association. There can be no doubt of the value of such an association as that of the public vaccinators, and we were surprised to find how small a percentage of public vaccinators have as yet availed themselves of the privilege open to them all of becoming members of the association. To have such an organisation through which to exchange views and to discuss new points arising in connexion with work common to all its members must be of great service and moreover the position of the public vaccinator is not yet so well defined or so suitably arranged that any means may be neglected by which to ensure his obtaining the consideration and facilities that his merits as well as the public welfare most decidedly demand. The secretaries of the association are Mr V A. Jaynes and Dr A E Cope and we strongly recommend public vaccinators who have not yet joined to become members of the association

PICTURES IN BACTERIA COLOURS

WHEN Mr Opie was asked what he mixed his colours with he replied perhaps not very courteously 'With brains Sir His meaning was of course perfectly clear Brains indeed do elaborate colours but Mr Opie could hardly have foreseen that the human brain would have worked out a method depending upon the production of colour by micro organisms For the most part the permanent pigments of the artist have a mineral composition although of course the study of organic chemistry has made available thousands of pigments derived from coal tar Organic colourings also—and very beautiful colourings they are—may be the product of certain species of bacteria Hence they are called chromogenic bacteria Bacteria are known which when placed in a suitable environment will produce almost all shades of colour In other words they evolve products which absorb part of the components of white light and return the residual component or components which may be a tint having more or less the purity of a primary colour of the spectrum Thus by cultivating various chromogenic organisms each on its proper patch on the canvas a picture with all the colouring that the colourman's art can produce may be obtained Sunset effects might in this way be produced by the micrococcus prodigiosus grown, say on a background of boiled potatoes This organism produces bright red spots and was doubtless responsible for the death by violence of many a victim who in bygone days was charged with having brought about the blood red spots that were occasionally found developed on various articles of food The same organism doubtless led to the occasionally reported miracle of 'the bleeding Host Again doubtless excellent seascapes could be produced by the selection of organisms producing yellow and blue colours respectively, a blend of colour suitable perhaps also for a moonlight scene and the purple-producing bacteria might be enlisted for the presentation of dawn A field of corn might possibly be faithfully coloured by growing the micrococcus aurantiacus on a suitable medium or for the same purpose the sarcinæ might be used which produce rich yellow colours although no sarcinæ producing blue violet or green colouring matters are as yet known A great variety of tints may be noted in certain cheeses and under certain circumstances, in the Stilton cheese in particular the tints of pink, red brown and green being respectively evolved *It is well known that the intense blue of* natural indigo is a product of the active life of bacteria In the province of Bengal alone the value of the output of indigo per annum is or was, something like two million of pounds sterling and it is astonishing to think that such a wealth of produce is gained by the labours of a microscopic organism now recognised as a distinct species and known as the bacillus indigogenus There is no telling what marvellous results the study of chromogenic organisms may lead to and it is not impossible that a picture will some day be produced in which the colours portrayed on the canvas will be the products of bacteria provided with a suitable pabulum

THE GOVERNMENT AND THE WATER-SUPPLY OF LONDON

MR LONG, the President of the Local Government Board was present on Wednesday night at a complimentary dinner given to Mr H S Samuel M.P, by his constituents in the east of London and he took occasion to make a most important pronouncement upon the London water question Mr Long definitely pledged the Government to introduce next session a Bill dealing with the matter and expressed confidence that the measure for which his department would be responsible would solve this difficult problem in an equitable and final manner We sincerely trust that Mr Long is not over sanguine for complete success will be difficult to obtain and failure will have far reaching consequences It is well known that the present Government does not favour the pretensions of the London County Council to be constituted the sole authority over the water supply of *London and Mr Long, while complimenting the great* municipal body upon its energy definitely foreshadowed the fact that the Government scheme would give the London County Council no predominant position Something of the nature of the measure which the Government will place before the country may be gathered from Mr Long's adjuration to the metropolis the suburban fringe and the immediate vicinity affected to consider the advisability of a give and take attitude He asks the residential neighbourhoods which loosely girdle London though in many cases outside the geographical limits of the County of London not to be too insistent upon what they conceive to be their uttermost rights in the matter of their water He would have them remember that proximity to the metropolis brings them incalculable advantages and he begs them to consider these in the nature of a *quid pro quo* His speech as far as it went indicates the intention of the Government to approach this difficult matter in a statesmanlike manner More than this we cannot now say

THE SPEED AND CONTROL OF MOTOR-CARS

THE series of accidents which have occurred in this country and in other countries during the past week is calculated to bring the motor car into disrepute and we counsel all interested in any way in motor-cars to do their utmost to suppress furious driving All motor car drivers should remember *that motor cars cannot be let loose* upon the streets like so many railway trains Present arrangements will not admit of it Until motor cars have a track of their own they must be placed under the strictest possible control in regard to speed and the rule of the road With motor cars coming round sharp corners at high speed pedestrians need almost a new sense The "pip pip is as a rule under these circumstances not a timely warning and people are likely to be run over before even they can realise that a motor-car is turning the corner It would be well enough if it were possible that certain tracks in our busy thoroughfares could be allotted to the motor car but that is not possible and therefore in the interests of the safety of the public this method of travelling must be kept within bounds The temptation to attain a high speed is we fear very strong when a driver knows that he is in possession of potentialities which neither overstrain nor exhaust his "petrol steed." It is difficult to enforce one set of rules for the country road and another set for the high streets of the towns, but, as we have said, such rules are necessary in order to protect the public. It cannot be gainsaid that the motor-car is by many people viewed with terror and alarm inspired through the fault of motor-car drivers themselves. The latter forget that a series of hundreds of explosions in order to gain motion is a new feature on the road as is the speed at which the motor-car is able to travel. We do not doubt that in due time the noise will be got rid of, but that achievement may likely enough prove a new danger. The temptation to increase speed will be more than ever. We could wish for some invention by means of which the speed of a motor-car could be automatically kept within legal bounds. Surely in these days of extraordinary engineering skill it would be possible to devise an arrangement attached to the axle of the motor-car which would check the speed of the car as soon as it rose to a certain and a dangerous point. The attachment of such an arrangement to a motor-car could be made compulsory and anyone found without such a method of control on his car could be fined. We have no wish to interfere with any advance in means of locomotion, but this advance must not be made at the expense of the public safety.

THE EFFECTS OF BURIAL AFTER AN EXPLOSION.

IN the *Deutsche Militärärztliche Zeitschrift* for May, p. 225, Dr. Herhold relates the cases of five men who were engulfed in the ruins of a powder magazine which exploded at Paoting-fou on Nov. 30th, 1900. Four out of the five victims were more or less completely buried in the débris, while the fifth was thrown violently to the ground, losing consciousness for a few minutes and subsequently exhibiting delirious symptoms during several days, with total amnesia regarding the events which immediately preceded the explosion. The body of one of the buried men was not recovered for between 50 and 60 minutes. The man had then been dead for some time, but one of his companions in misfortune declared that he felt him stirring beneath him for 10 or 15 minutes after they were engulfed. At the necropsy the lungs were found to be intensely congested with sanguineous effusion into the pleural cavities, and there were also blood-clots in the right side of the heart. The rescue party succeeded in freeing the head of another of the victims after about 25 minutes, but 15 minutes more elapsed before the whole of his body was brought to the surface. He was a man of very great chest capacity, and said that he had been able to breathe quite freely until his comrades by their trampling overhead occluded the air crevices. When exposed his skin was deeply cyanosed and for some little time he remained semi-delirious. Another of the men was rescued after he had been completely buried during at least 20 minutes. At first he, too, was able to draw his breath with comparative freedom, but gradually the supply of air seemed to be shut off, until finally the act of respiration amounted to the most intense agony. In conclusion, Dr. Herhold lays stress upon the great importance in similar cases of preserving the patency of all channels through which the air can possibly reach the buried persons. The utmost promptitude in attempting to rescue them is, of course, essential, but misdirected efforts are worse than useless. Whenever practicable it would be well to commence proceedings by an excavation at the side of the spot where the victims are believed to be lying. A short horizontal tunnel can then be driven with a minimum risk of interfering with the air-supply. Should the exact position of the buried individuals be known it ought to be possible to insert ventilating tubes for their relief, but all indiscriminate explorations of this nature are fraught with danger. In cases where access in the desired direction is only attainable from above it may often be possible to avoid trampling on loose detritus by utilising planks or beams resting on trestles, blocks of wood, large stones, or any other supports that may be available.

MENTAL DISORDERS FOLLOWING INFLUENZA.

IT is now a well-recognised fact that mental disorders are more frequent after influenza than after any of the other zymotic diseases. In the April number of the *Journal of Mental Science* Dr. George A. Rorie, medical superintendent of the Cumberland and Westmorland Asylum, gives an account of insanity following influenza, with statistics of 68 cases. An increase in the admissions of patients suffering from melancholia during or after epidemics of influenza has been reported from several of the asylums of this country—*e.g.*, Hanwell, Birmingham, Nottingham, and Edinburgh. On examining the statistics of admissions into the Cumberland and Westmorland Asylum Dr. Rorie finds a similar increase in admissions of melancholic and suicidal patients during the general epidemics of influenza. "The increase in the admission of melancholic patients is specially marked in the years 1891, 1893, and 1896, while there is a marked increase in the admission of suicidal cases during the years 1890, 1893, and 1895." During the period from 1890 to 1900 68 cases of insanity, in which influenza was the chief predisposing or exciting cause, were admitted to the Cumberland and Westmorland Asylum. Besides these, says Dr. Rorie, there were other numerous cases, some of which were partly due to influenza, but these have not been included in the paper which takes account only of those wholly due to influenza. Of the 68 cases there were 34 males and 34 females. Taking the males it was found that the average age on admission was 43·8 years. Six were between the ages of 61 and 70 years, and 10 were between the ages of 21 and 30 years. Among the females the average age was 49·5 years, which is rather older than the males. The greatest number were between the ages of 41 and 50 years. The question as to the exact time of the appearance of mental symptoms after an attack of influenza was difficult to answer. In some cases it seemed to follow directly on the attack of influenza or at an interval of a few days, in other cases weeks or months seemed to have intervened. In many cases the patient's friends stated that the patient had never been the same mentally after an attack. These results concur with those published 10 years ago by Dr. Leledy in his work on "Influenza and Mental Disorder." Most commonly an interval of from one to three months would elapse between the attack of influenza and the commencement of melancholia, mania, or other form of mental disorder. A notable feature was the large proportion of suicidal cases in both mania and melancholia. Thus of a total of 34 male patients 17 were suicidal, 16 of these being cases of melancholia and one of mania. Of the 34 female patients there were 19 suicidal cases, of which 14 had melancholia and five mania. The type of melancholia varied a good deal: in some cases it was simple melancholia with listlessness and loss of appetite, in others there was a certain amount of mental confusion and impairment of memory, with a frequent tendency to stupor, especially in the female cases. In some cases the patients were resistive, had delusions of persecution or poisoning, and refused to take food Hallucinations were noted in five females and three males; these were usually of hearing, but hallucinations of sight and feeling were also met with. The cases of acute mania among the men were all at a considerable period after the attack of influenza; among the females, on the other hand, two out of four cases of acute mania followed soon, if not directly, after the attack. One of the male patients aged 42 years, rapidly developed symptoms of general paralysis after influenza and died seven months after admission. Dr Rorie concludes that mania is the least favourable form of insanity following influenza as regards prognosis. In patients already insane the effect of an attack of influenza led to little change in the majority of cases but two cases of delusional insanity under Dr Rorie's care became markedly worse giving freer utterance to delusions of persecution and one case of melancholia became distinctly more depressed.

MILK UNDER THE FOOD AND DRUGS ACT

A MILK SELLER was summoned recently before Mr Marsham at the instance of the Holborn Borough Council for selling milk from which 8·6 per cent of the fat had been abstracted, and she was ordered to pay a fine. Upon this a member of the firm from which the milk had been originally purchased asked that the second sample reserved might be sent to the Commissioners of Inland Revenue for analysis and in this request the defendant joined. The milk however as might have been expected under the circumstance had during the time that had elapsed since it left the cow undergone natural processes which rendered its analysis for the determination of the question before the court impossible to conduct satisfactorily. The precaution of adding a few drops of a preservative—of course not in sufficient bulk to influence the analysis—had not been taken. Mr Marsham accordingly said that he had no alternative but to dismiss the summons as the defendant had a right to have the milk analysed at the Government laboratory. This unsatisfactory termination of the case is due to the 21st Section of the Food and Drugs Act of 1899 which enacts that "the justices or court referred to in Section 22 of the Sale of Food and Drugs Act, 1875 shall on the request of either party under that section cause an article of food or drug to be sent to the Commissioners of Inland Revenue for analysis and may if they think fit do so without any such request." The section of the Act of 1875 referred to said "The justices may in their discretion cause any article of food or drug to be analysed by the Government analyst," a very different provision and one which we should have thought adequately protected both parties without offering to the defendant in certain cases a simple method of escape dependent only on the question of whether the article of food which he was selling was of a perishable nature or not. We are not aware of any tendency on the part of analysts acting for local authorities to make mistakes or unduly to emphasise the case against local defendants by making incorrect analyses or of any magic attaching to analysis in a Government laboratory. Admittedly differences of opinion may arise in obscure and difficult analyses and a witness called by one side may draw inferences differing from those drawn by one called by the other side. On such an occasion a third opinion is obviously useful whereas it is not wanted when a defendant has cast no doubt upon the evidence brought against him. But it seems to us that unless the precaution of adding a minute quantity of a preservative be taken most prosecutions connected with the sale of milk, and some with regard to other articles of diet will in hot weather at all events, be futile. Possibly, however the magistrate can be asked and will be willing in all cases to send the second sample to the Government analyst directly it is taken and before the case is heard.

OUR readers will regret to hear of the serious illness of Mr Jordan Lloyd. On Tuesday evening June 25th Mr Jordan Lloyd presented symptoms of acute appendicitis, and as they grew more severe an operation was decided upon on the following Thursday morning. The operation was performed by his colleague Mr Bennett May when a perforated and gangrenous appendix was removed. We are glad to say that during the anxious week that has elapsed since the operation Mr Jordan Lloyd's progress towards recovery has been steady.

DR GLOVER informs us that it is his intention to offer himself for re election as one of the Direct Representatives for England and Wales. It is understood that Mr Victor Horsley will resign his seat and that he and Mr G Brown will also seek re election. Mr Horsley at his original by election stated that he would resign at the same time as his colleagues tenure of office terminated that the expense of two elections might be obviated.

THE quarterly meeting of the Society for the Study of Inebriety will be held at 11, Chandos street, Cavendish square, W, on Tuesday July 9th at 4 P M when a paper will be communicated by Dr T N Kelynack and Mr W Kirkby F L S on Arsenical Poisoning from Beer Drinking in its Relation to the Study of Inebriety. The President Dr Wynn Westcott will be in the chair. Visitors are cordially invited.

DR J LORRAIN SMITH has been appointed a member of the Commission to inquire into the present condition of the higher, general and technical education available in Ireland outside Trinity College Dublin and to report as to what reforms if any are desirable in order to render that education adequate to the needs of the Irish people.

HIS MAJESTY THE KING has been graciously pleased to continue the privilege of the Royal Patronage to the National Sanatorium for Consumption and Diseases of the Chest at Bournemouth of which charity her late Majesty Queen Victoria had been a patron since the year 1869.

WE understand that the Committee appointed by Mr Brodrick to consider the War Office scheme for the re organisation of the Army Medical Service will hold its first meeting to day (Friday).

THE Madrid *Correspondencia* of June 26th states that 12 cases of plague and four deaths have occurred at Oporto.

ROYAL NAVAL HOSPITAL, HASLAR

THE session of instruction at the Royal Naval Hospital Haslar terminated on June 26th when the 14 surgeons under instruction who had obtained their commissions after the competitive examinations in London some months previously received appointments to His Majesty's ships on the determination of their seniority by the sum total of the marks obtained in London and at Haslar. The following prizes were awarded—viz the gold medal to Surgeon A J Wernet and the microscope and the silver medal and books to Surgeon E Cox. The Director General of the Medical Department of the Royal Navy Sir Henry Norbury K.C.B., in distributing the prizes complimented all the officers highly on the very favourable report which he had received from the inspector general and the officers of the professorial staff as to the great interest which they had shown in the subjects which formed the course as well as on the general zeal and ability that they had evinced during the time they had been under instruction.

ARMY MEDICAL SCHOOL, NETLEY.

THE eighty-second session of the Army Medical School, Netley, was brought to a close on June 29th, when the prizes were distributed and an address was delivered by the Right Honourable the Earl of NORTHBROOK, G.C.S.I., in the presence of a distinguished company which included Surgeon-General A. F. Preston (acting Director-General, Army Medical Service), Surgeon-General R. Harvey, C.B., D.S.O. (Director-General, I.M.S.), Surgeon-General Sir Joseph Fayrer, Bart., K.C.S.I., Surgeon-General W. R. Hooper, C.S.I. (President of the Medical Board, India Office), Sir Alfred Lethbridge, K.C.S.I., Colonel H. Cayley, and the military staff of the Royal Victoria Hospital.

The proceedings were opened by Colonel K. MACLEOD, who read a satisfactory report on the work of the session of the school and announced the following awards: Herbert prize of £20, in memory of the late Right Honourable Sidney Herbert, awarded at the end of each course of instruction to the surgeon-on-probation who has evinced the highest proficiency in the special subjects taught in the school: G. E. Charles, I.M.S. Martin Memorial gold medal, to commemorate the late Sir Ranald Martin, C.B., given to the surgeon-on-probation who takes the highest place in military medicine: G. E. Charles, I.M.S. The Professor of Medicine called attention to the names of Surgeons-on-Probation A. G. McKendrick, N. E. H. Scott, and F. W. Sumner as having particularly distinguished themselves in military and tropical medicine. The Parkes Memorial bronze medal given to the surgeon-on-probation who takes the highest place in hygiene, part of a memorial to commemorate the great services of the late Professor E. A. Parkes, F.R.S. : G. E. Charles, I.M.S. Second prize in hygiene, a book presented by Mrs. de Chaumont in memory of her husband, the late Professor F. de Chaumont, F.R.S. : Surgeon-on-Probation W. C. Stevenson, R.A.M.C. The following surgeon-on-probation was mentioned as having particularly distinguished himself in military hygiene: O. St. J. Moses, I.M.S. The Montefiore prizes, founded by the late Mr. Nathaniel Montefiore — First prize, medal with cheque for £21: O. St. J. Moses, I.M.S. ; second prize, a revolver: G. E. Charles, I.M.S. The Professor of Military Surgery named the following surgeons-on-probation as deserving of honourable mention for their knowledge of military surgery: J. W. Little, I.M.S., and J. O. Barnes, I.M.S. Prize in Pathology, books presented by Sir Joseph Fayrer, Bart., K.C.S.I. : F. W. Sumner, I.M.S. ; while the names of the following officers were mentioned as worthy of special mention as pathologists: G. E. Charles, I.M.S., and W. D. Ritchie. I.M.S. Maclean prize, books presented in memory of Surgeon-General Maclean, C.B. : A. G. McKendrick, I.M.S., who obtained the highest marks in chemical and ward work. Colonel Macleod said that he had much pleasure in announcing that a new prize, consisting of a bronze medal and £5, had been established by Mrs. W. Marshall Webb in memory of her husband, the late Surgeon-Major-General William Marshall Webb. The subject of competition would be Hospital Administration, which was selected by the Senate, to whom the choice was entrusted by Mrs. Webb, as one of peculiar importance and of special fitness in view of the fact that the late Surgeon-Major-General Webb held the office of assistant professor of military medicine in the school. The prize would be open for competition next session. Colonel Macleod then invited Lord Northbrook to distribute the prizes.

Lord NORTHBROOK, on handing the prizes to the successful competitors, said a kindly word to each and then gave an address which lasted some 20 minutes. He commenced it by offering his congratulations to the prize-winners and said that in his own experience he had observed that many men who had distinguished themselves as prize-winners at the universities had gone on to most distinguished careers in after life, but while this was so many of those who had risen to high positions, especially in politics, had not been prize-winners and had only really commenced to educate themselves after their so-called college training was over. He hoped that the present success of the prize-winners at Netley was but an earnest of greater success in the future. Speaking specially of the Indian Medical Service, he reminded the young officers of the great field of work open to them, not only in their own profession but in that of political life in India and in other departments of the public service outside their own professional calling. He said that he would like to mention four names of men which occurred to him, all of whom had done excellent work for India. The first was that of the late Dr. Bellew, who did such excellent work as a frontier political officer when he went on the famous mission to Kandahar with Sir Harry Lumsden and who was selected by Lord Lytton as the man most fit for the post of chief political officer with the army of Kabul. Surgeon-General Bellew was a centre of influence all along the frontier and Lord Northbrook repeated the remark made long ago by a prominent Indian politician that "Dr. Bellew's moral force among the natives of the frontier was equal at times to the physical force of three battalions of infantry." The second name was that of Sir George Robertson who conducted the defence of Chitral and who was so well known for his work as a frontier political officer. He then referred to Colonel Cayley who after doing good work in India held a professorship in the Army Medical School and since his retirement had been through the African war as the head of the Scotch Red Cross Hospital. The fourth name was that of Lieutenant-Colonel E. Lawrie, I.M.S., of Hyderabad, who had distinguished himself in connexion with the Chloroform Commission. In speaking of the prizes gained in the school, Lord Northbrook said that the one named after Sidney Herbert, under whom he had served as Under-Secretary of State for War about the time when he had been removed to the House of Lords as Lord Herbert of Lea, commemorated a great Secretary of State, and one of the value of whose work he was personally well aware as the introducer of the improvements into the army after the Crimean war with the assistance of Miss Florence Nightingale. He quoted this lady's letter to Lord Salisbury urging the benefit of the expenditure of treasure in trying to prevent the waste of life from disease in campaigns by perfecting, as far as possible, the medical arrangements. Lord Northbrook said that he noticed that most of the prizes were in memory of distinguished professors of the school. There was, in his opinion, no better way of commemorating their work. He was especially glad to hear of the new prize which had been established by Mrs. Webb in memory of her husband, the late Surgeon-Major-General William Marshall Webb who had formerly been an assistant professor of medicine in the school. He was, he said, old enough to remember the Crimean war and the fault-finding which was general all over the country with the bad administration of the army. Such complaints, if true, had to be suffered for. At the time of the Crimean war they were true and they ended in the fall of the Ministry and in Lord Aberdeen being turned out of office. During the present war complaints had been made about the administration of the army in South Africa, complaints as to the transport and supplies, and specially as to the administration of the medical service. The latter had been inquired into and found creditable. At first all sorts of complaints were made, but now the public were satisfied and they ought to congratulate themselves on all that had been accomplished. A Royal Commission had inquired into the working of the Royal Army Medical Corps in South Africa and found that it had been satisfactory, though it had pointed out certain defects. Referring to the report of the Commission he quoted the concluding paragraph, which he specially drew attention to: "And all witnesses of experience in other wars are practically unanimous in the view that, taking it all in all, in no campaign have the sick and wounded been so well looked after as they have been in this," and he asked the pertinent question—To whom is the credit due? He said that the Secretaries of State as a rule were only a short time in office, and that unless they were exceptional men like Lord Cardwell, though they might do conscientious work they left no particular record of their day. The credit of the success was due to the patient attenders to details who had worked quietly for years and to the military authorities. In this connexion he mentioned H.R.H. the Duke of Cambridge, Lord Wolseley, Sir Redvers Buller (the Adjutant-General), General Brackenbury, and especially Sir Coleridge Grove and the late Director-General of the Army Medical Service, Surgeon-General J. Jameson, the last-named of whom made a success by means of the bond of sympathy which existed between himself and the officers serving under him and the great civil profession of medicine without which what had been accomplished would have been impossible Coming to the personal part of the medical arrangements of the South African campaign he reminded his audience that when the war broke out two army corps were sent to South Africa and that the Director General of the Army Medical Service, owing to the undermanning of the Royal Army Medical Corps, could only with difficulty provide a sufficient number of medical officers to accompany them but later it was found that more army corps were required and a total force of 250 000 men had to be provided with medical aid The question was how the great want was to be supplied It was met, said Lord Northbrook, "by the patriotism of the people Men had come forward from the universities and schools, the medical officers of the auxiliary forces had volunteered, men had given up their lucrative private practices, the colonies had supplied medical men, private hospitals had been organised, and the St John Ambulance Association, of which the late Lord Wantage had been so prominent a member, had given its invaluable help in the nation s difficulty" The result had been that at the time of the publication of the Blue book, the medical staff in South Africa consisted of 479 officers of the Royal Army Medical Corps, of nine consulting surgeons and physicians of 385 civil surgeons, and 431 nurses, and, said Lord Northbrook, "I do not think that these were the maximum numbers, for in a speech not long ago Mr Brodrick spoke of 700 admirable recruits which the medical profession had furnished" He extolled the way in which the professional work had been done in South Africa and said that in spite of difficulties which were considered incredible, the pluck perseverance, and capacity of the Royal Army Medical Corps had carried them through "No class of officers had had greater difficulties to contend with, yet none had achieved greater success" The Royal Commission had endorsed this verdict and the truth of it was recognised by impartial witnesses Than this verdict no higher praise could be given. Individual members of the corps had won well merited rewards, for of the greatest distinction which could be won by a soldier, the Victoria Cross no less than four had been awarded to officers of the Corps—Lieutenant-Colonel W Babtie, Captain E T Inkson, Captain W H S Nickerson, and Lieutenant H E M Douglas—besides promotions and other honours They must, however, look to the future The Royal Commission had recommended that an inquiry should be made into the medical arrangements of the army Lord Northbrook said that he did not dare to offer an opinion on the questions involved, for he had no right to offer one, but it was right that Mr Brodrick should carry out the intentions expressed and he hoped that the anticipations of the Secretary for War would be realised Speaking at the dinner to the South African civil surgeons Mr Brodrick had said that "they had an organisation on which might be founded not merely something which was effective, but something which, as their experience was most recent entitled them to [illegible] army which would place [illegible] peoples" Lord North[illegible] organisation of the corps he had two observations to make—one was that the staff of the Royal Army Medical Corps should be permanently increased, and the other was that its members should have opportunities granted them of keeping themselves up to the highest standard of professional knowledge The great growth of medical science had necessitated specialists and in the future special work and specialists would certainly increase He saw no reason why the Royal Army Medical Corps should not have its own specialists—officers who had been afforded opportunities of studying under the best men and who themselves would become experts, such opportunities would ensure efficiency and attract some of the best men from the school of the corps The second observation was that he hoped the committee s inquiry would extend to the working of the transport and the financial departments and to the working of the War Office itself in relation to medical matters Referring to the teaching which the young officers had received at Netley he spoke of the advantage they had enjoyed in listening to Colonel Stevenson than whom no one could inform them better of all the changes which had occurred in wounds due to the alteration in weapons While, however the care of wounded men was of the greatest consequence the records of this South African campaign had but endorsed the experience of former wars that disease worked more havoc than the bullet He congratulated them on having had the opportunity of studying under Dr Wright, of whose work he had himself some knowledge, for as a member of the Indian Plague Committee he had visited his laboratory, and he considered him to be a man who worked on the sound grounds of experimentalism. He had the confident hope that the progress of science would lead to increased prophylaxis whether by inoculation or otherwise Lord Northbrook concluded by recalling the scene in the Royal Victoria Hospital when their late beloved Queen near the end of her great career shed the light of her presence in the wards of the hospital and on the suffering soldiers there whom she had loved so well No one of them would ever forget the late Queen s sympathy, and he knew the King would take the same kindly interest in the hospital and in his soldiers

Sir **JOSEPH FAYRER** subsequently addressed a few words of congratulation to the young officers and thanked Lord Northbrook for his address

The proceedings were brought to a close by Colonel **CHARLTON** principal medical officer at Netley Hospital, who wished the young officers God speed, and expressed the hope that they would in years to come look back on pleasant days spent at Netley

The following lists show the positions of the young officers recommended for commissions in the respective services —

COMPLIMENTARY DINNER TO SURGEON-GENERAL JAMESON, C B

MR. G **LENTHAL CHEATLE**, one of the honorary secretaries, has sent to us the following list of names to be added to those which we published in our issue of June 15th, p 1708 as those of members of the medical profession and others who have signified their wish to do honour to the late Director General of the Army Medical Service —The Right Hon. Lord Halliburton, Colonel Sir Howard Vincent, M P, Sir Hugh Beevor Bart, Sir John Turley, Sir Samuel Wilks Bart, Dr James Little Regius Professor of Physic, University of Dublin Dr Ball, Regius Professor of Surgery, Trinity College, Dublin, and Mr Thomas Bryant, Mr Pearce Gould, Mr H H Clutton, Surgeon General R. Harvey C B, D S O, Surgeon General W R. Hooper, C S I, and Mr A D Fripp C B C V O There is no need for us to wish the occasion success—success is already assured, and the dinner promises to afford remarkable witness to the appreciation in which Surgeon General Jameson and his services to his country are held by the members of his profession.

THE MIDWIVES BILL.

LORD BALFOUR OF BURLEIGH, in moving the adoption of the report at the eighth annual general meeting of the Association for Promoting Compulsory Registration of Midwives, held at 47. Cadogan-square, London, S.W., on June 26th, said :—

I have no right to attend this meeting as a member of the Government, and you will please remember that I am here only in my private and unofficial capacity. The objects of this association came first under my notice before I became a member of Her late Majesty's Government. I never can forget the first beginning of the persuasion which was exercised upon me to bring this somewhat difficult and unpleasant subject before the House of Lords. I did so because when I looked into the case for the Bill I found it was so strong that it would have been a dereliction of duty if I had not done everything in my power to help on the cause. As to the use of deputations I may say that during six years of my official life I have had to deal with many deputations and I have not got a very profound belief in the utility of deputations. Perhaps that is because I see too much from the inside of the working of these matters. I have never in the whole course of my experience ever had to do with a case which on its pure merits, apart from all other considerations, seems to me to present such an overwhelming need for legislation. I myself think that many deputations know that they ought not to be granted what they ask for and a considerable proportion feel that it would not be good for them if they got what they demanded. That being my view of the ordinary case as presented by deputation I wish you to notice that the cause of your association is the one outstanding exception which justifies the most persistent and the most continual agitation until you are successful, and I agree with what Mr. Johnstone has told you that you have a very strong case indeed. You have greatly strengthened your position since the days when I first came into the association and you are, I think, assured, if you will only go on on the same lines, of a certain and not far distant triumph. One thing I am certain of is that you need not fear public discussion. The more the matter is discussed the greater will be the conviction of the extreme strength of your case Your cause is that of the majority of the wives of the working men and of the more humble portions of the population of this country. The case against you is that of those who are interested in maintaining the existing state of affairs. I consider that those who have been midwives and who practise under that name are entitled to fair consideration. A large majority are competent and their interests must be considered, otherwise it would be unjust to those who are honestly endeavouring to make a living and who in the main are doing their very best. The fact, however, that there are grave and far-reaching abuses under the present condition of affairs makes it clear that no private interest ought to be allowed to stand in the way of reform. I would rather not speak of the other class who are interested in this proposed measure because I think you have dealt with it—I mean the professional opposition to your Bill. I consider that where it is not merely selfish it is foolish, because you do not want—and I think this is a point to be emphasised—you do not want to do anything to undermine professional etiquette or to attack the proper medical standing of professional men. I have always pointed out that the medical profession being beyond all others a humane and unselfish profession its first anxiety is to do the best for a patient at the earliest possible time for the saving of life. If, therefore, medical men are assisted by skilled midwives they would be more certain of having early information that danger exists than if the patients are attended by unskilled women ignorant of danger or possibly too selfish to trouble or perhaps afraid of allowing anything to be known. I believe it to be a necessity that in the classes concerned the attendance in these cases must be furnished by women for women. What you want to provide for is that minority of cases where danger can be foreseen and thus avoided; often it is a question merely of hours. I believe that in these circumstances the elementary training which your association seeks to secure for these attendants would make it more certain that the medical man would have the note of warning sounded in his ears and thus early intelligence would be furnished to those who can best remedy the danger. I was recently at the College for the Blind at Norwood and the director of the institution told me that on admission every child—and there are always some hundreds there—is examined by a skilled oculist. Experience over a long series of years leads this gentleman to say with certainty that about 72 or 73 per cent. of those who pass through the College need not have been sent there if they had enjoyed the benefit of proper care in their early years. I do not say that all these people by this early attention could have been made into really seeing people in the ordinary acceptation of the term, but they would have had the power of perception of light from darkness and of movement from absolute rest. I do not say that 70 per cent of the cases of blindness are caused by improper care at birth, but certainly a large proportion are. I believe it amounts to about 30 per cent. Now, that fact of itself is most startling and I believe it to be an undoubted fact and one that might well be included in the pamphlets of the association. You should keep this Bill out of the morass of Government measures and go on as you have been doing. You should endeavour to get a discussion on the earliest possible Wednesday next session and then strive to take off as much of the opposition to it as you can. Thereupon pressure can be brought to bear in the proper quarters on those who manage these things so as to give you a chance. I can only assure you that if opportunity offers for the consideration of the possibility of giving this most serious and necessary legislation a helping hand from the inside you may, so far as my duty allows it, always count upon me. There are, however, limitations, and you must remember that if I cannot do all that I would like to do it is certainly not from want of interest, and I can assure you that I wish your association the earliest possible success.

ANNUAL DINNER OF THE EPIDEMIOLOGICAL SOCIETY OF LONDON.

THE dinner to celebrate the fifty-first anniversary of the foundation of this society was held on June 28th at the Grand Hotel, Trafalgar-square, W.C., Dr. Patrick Manson, C.M.G., F.R.S., the President of the society, occupying the chair. The guests of the society were Sir William S. Church, Bart., President of the Royal College of Physicians of London; Sir Montague Ommanney, K.C.M.G., Permanent Under Secretary for the Colonies; and Professor T. Clifford Allbutt, F.R S. Among others present were Dr. W. A. Bond, Dr. G. S. Buchanan, Dr. H. T. Bulstrode (honorary secretary), Dr. W. H. L. Copeland, Dr. A. D. Cowburn, Major A. M. Davies, R.A.M.C., Dr. J. R. Delmege, Dr. W. E. Fletcher, Sir Francis Lovell, C.M.G., Dr. Bruce Low, Dr. Hector Mackenzie, Mr. Shirley Murphy, Mr. W. C. C. Pakes, Dr. Franklin Parsons, Mr. F. G. Parsons, Dr. E. C. Seaton, Dr. Arthur Shadwell, Dr. W. R. Smith, and Dr. B. A. Whitelegge.

Sir William Church, in proposing the toast of "The Imperial Forces," dwelt upon the heroism of our troops of all grades at Ladysmith, Graspan, and other places. The behaviour of our soldiers under most trying climatic conditions clearly demonstrated that there were no indications of degeneration —Major A. M. Davies, R.A.M.C., in replying for the army, referred to some of the difficulties with which the Army Medical Service had recently been confronted in South Africa. It was impossible to wage war without some inconvenience and hardship, and obviously when a hospital intended to provide for at most 500 men was called upon to deal with double or treble that number, the elasticity of the administrative machinery was liable to become somewhat strained.—Dr. W. R. Smith, who replied for the auxiliary forces, pleaded for a more careful study of the causes and behaviour of disease in modern warfare and for the necessity of the presence of independent and skilled epidemiologists from the beginning of a campaign.—Dr. Whitelegge, His Majesty's Chief Inspector of Factories, who proposed "The Visitors," drew attention to the manner in which fresh infectious processes were daily being brought to light, and he added that quite recently his colleague. Dr. T. M. Legge of the Home Office, had discovered a new infection connected with the fish-curing industry. There was still much to be done in studying the diseases and drawbacks connected with industrial occupations.—Sir Montague Ommanney, in replying [illegible] he efforts [illegible] Our vast [illegible] umerable [illegible] onditions which obtained in some of our Crown colonies were such as to sap continuously the "energy of initiation." No one, he assured them, felt a keener interest in the importance of improving the condition of our more unhealthy colonies than Mr. Chamberlain, and he felt sure that the Colonial Office would continue to extend a helping hand to epidemiological research.—Professor Clifford Allbutt thought that in the near future preventive medicine would take a very leading place in the medical profession, and it was probable that the profession as a whole would occupy a more definite relation to the State than was the case at the present moment. He welcomed, with other speakers, the great change which had come over the administration of the Colonial Office in the direction of encouraging original research.—Dr. Patrick Manson, in proposing the toast of "The Epidemiological Society of London," pointed out that the work that the society performed was of a quiet and unostentatious character, but he trusted that such work was not without its value. The science of epidemiology was, he thought, in an extremely flourishing condition and its energy had received cordial support from the Colonial Office. He regarded it as almost providential that at the present time when there was so much work to be done and when apparently the psychological moment had arrived they had at the Colonial Office Mr. Chamberlain and at the Royal Society Lord Lister. Epidemiology had in the past been somewhat warped from the fact that man had for a long time regarded the infectious diseases as his own prerogative, but they had now to recognise the important fact that they shared many diseases with the lower animals, and it was only when this fact was accorded its proper value that the natural history of infectious disease would be properly comprehended. Dr. Manson drew attention to the large number of scientific expeditions which had recently left our shores, and he added that the Epidemiological Society was now assisting in the despatch of an *expedition to the Pacific Islands* to study some of the problems connected with malaria. The Mercers' Company had made a liberal contribution towards the funds, and he trusted that if the generous example set by the Liverpool merchants in assisting the Liverpool School of Tropical Medicine were followed by some of our wealthy London merchants the expedition in question would be able to start at the end of the year.—Sir Francis Lovell, proposed "The Chairman," whose name was, he added, regarded in the colonies as "synonymous with malaria."—Dr. Bulstrode, who replied to the toast of "The Officers of the Society," reminded his hearers of the remark made by Professor Haffkine at a recent dinner to the effect that inasmuch as the opportunities of the British empire for the prosecution of epidemiological research were altogether unique, the world of science had a right to expect that the English Government would make proper use of such opportunities.

PLAGUE IN EGYPT.

Two further reports issued by the Director-General of the Egyptian Sanitary Department have been forwarded to us. They run as follows:—

"Since my report addressed to your Excellency on June 9th we have received no information of any towns other than Zagazig and Minieh being infected with plague.

The total number of cases of plague reported from these two places during the week was 18, 17 from Zagazig and one from Minieh; 14 of these were admitted to hospital and four were found dead outside hospital. In addition five deaths took place among the patients in the Government hospital. No notice of any European being attacked by the disease has been received during the week.

The town of Zagazig is no doubt somewhat seriously infected, and from inquiries that have been made by Major Garner it would appear that for some time previously to the discovery of the first cases many of the inhabitants of the different quarters of the town had noticed rats in a dazed condition and dying; this mortality among the rats was first remarked at the time of a heavy rainfall in May, the date of which was May 14th.

The staff at Zagazig has been largely increased during the week, and the general cleansing and disinfection of the whole town is being carried out rapidly."

During the week ending June 23rd 25 cases of plague have been reported throughout Egypt, among which eight deaths have occurred—six in hospital and two out of hospital. Of these 25 cases 19 have occurred at Zagazig, two at Alexandria, one at Minieh, two at Kafr El-Mansura (a small suburb of Minieh), and one at Port Said. Of the deaths four occurred in hospital at Zagazig; two patients were found dead out of hospital in the same town, one died in hospital at Minieh, and one in hospital at Port Said.

During the last few days there has been a marked improvement in Zagazig, and I trust that this will be maintained, indeed I have every reason to think that it will be. Only one case followed by death has occurred in the town of Minieh itself; the other two cases shown as coming from Minieh, as is mentioned above, occurred in a small Kafr close to Minieh Every house in this Kafr has been thoroughly disinfected and limewashed and I do not anticipate any further extension of the disease there.

The case found at Port Said occurred in the person of a young Greek who for some time had been out of employment and had lived in a dirty underground cellar. This single case, occurring after so many months of immunity at Port Said, was possibly due to rat infection.

The mortality among the cases treated in hospital is not high and reports reach me that most of the cases remaining under treatment in hospital are progressing favourably.

Suspicious cases have been reported from several different places during the week; each case has been carefully examined and not one of them has proved to be a case of plague."

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6377 births and 3247 deaths were registered during the week ending June 29th The annual rate of mortality in these towns, which had been 14·5 and 15·0 per 1000 in the two preceding weeks, declined again last week to 14·8 per 1000. In London the death-rate was 13·9 per 1000, while it averaged 15·4 in the 32 large provincial towns. The lowest death-rates in these towns were 8·5 in Cardiff, 9·3 in Croydon, 9·8 in Leicester, and 10·1 in Bristol: the highest rates were 17·8 in Oldham, 19·1 in Newcastle, 20·2 in Liverpool, and 21·7 in Preston. The 3247 deaths in these towns included 399 which were referred to the principal zymotic diseases last week, against 357 and 356 in the two preceding weeks; of these, 114 resulted from measles, 83 from diarrhœal diseases, 81 from whooping-cough, 53 from diphtheria, 46 from scarlet fever, 21 from "fever" (principally enteric), and one from small-pox. No death from any of these diseases was registered last week in Huddersfield; in the other towns they caused the lowest death-rates in Brighton, Plymouth, Cardiff, and Oldham, and the highest rates in Wolverhampton, Birkenhead, Salford, Blackburn, Bradford, and Sheffield The greatest mortality from measles occurred in West Ham, Wolverhampton, Birmingham, Birkenhead, Hull, and Gateshead; from scarlet fever in Preston; from whooping-cough in Swansea, Wolverhampton, and Bradford; and from diarrhœal diseases in Liverpool, Bolton, Blackburn, and Sheffield. The mortality from "fever" showed no marked excess in any of the large towns The 53 deaths from diphtheria included 18 in London, eight in Sheffield, five in Bristol, and three in Manchester One fatal case of small-pox was registered in London, but not one in any other of the 33 towns; four small-pox patients were admitted into the Metropolitan Asylums Hospitals during the week ending July 29th, and five remained under treatment on Saturday last. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2821, against numbers increasing from 1522 to 2707 on the nine preceding Saturdays; 408 new cases were admitted during the week, against 314, 323, and 368 at the end of the three preceding weeks The deaths referred to diseases of the respiratory organs in London, which had declined from 240 to 150 in the four preceding weeks, further decreased last week to 171, and were 42 below the corrected average. The causes of 45, or 1·4 per cent., of the deaths in the 33 towns were not certified, either by a registered medical practitioner or by a coroner

All the causes of death were duly certified in Bristol, Salford, Bolton, Newcastle, and in 12 other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Manchester, Preston, and Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 16·9 and 18·6 per 1000 in the two preceding weeks, declined again to 17·3 per 1000 during the week ending June 29th, but showed an excess of 2·5 per 1000 over the mean rate during the same period in the 33 large English towns. Among these Scotch towns the death-rates ranged from 9·5 in Perth and 10·0 in Leith to 18·6 in Glasgow and 19·0 in Dundee. The 552 deaths in these towns included 30 which were referred to whooping-cough, 25 to measles, 24 to diarrhœa, four to diphtheria, two to scarlet fever, and one to small-pox, but not one to "fever." In all, 86 deaths resulted from these principal zymotic diseases last week, against 75 and 97 in the two preceding weeks. These 86 deaths were equal to an annual rate of 2·7 per 1000, which was 0·7 per 1000 above the zymotic death-rate during the same period in the 33 large English towns. The fatal cases of whooping-cough, which had been 32 and 44 in the two preceding weeks, declined again last week to 30, of which 14 occurred in Glasgow, seven in Edinburgh, five in Dundee, and two in Paisley. The deaths from measles, which had been 17 and 25 in the two preceding weeks, were again 25 last week, and included 15 in Glasgow, four in Dundee, two in Leith, and two in Greenock. The fatal cases of diarrhœa, which had been 18, 17, and 13 in the three preceding weeks, rose again last week to 24, of which 11 were registered in Glasgow, four in Edinburgh, three in Dundee, three in Paisley, and two in Greenock. The deaths from diphtheria, which had been three in each of the two preceding weeks, increased to four last week, and all occurred in Glasgow, where the two fatal cases of scarlet fever and the death from small-pox were also registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 101 and 92 in the two preceding weeks, rose again last week to 95, but were slightly below the number in the corresponding period of last year. The causes of 27, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been 19·6 and 20·2 per 1000 in the two preceding weeks, declined again to 18·2 during the week ending June 29th. During the 13 weeks ending on that date the death-rate averaged 24·7 per 1000, the rates during the same period being 14·7 in London and 20·8 in Edinburgh. The 131 deaths of persons belonging to Dublin registered during the week under notice were 14 less than the number in the preceding week, and included five which were referred to the principal zymotic diseases, against eight and 10 in the two preceding weeks; of these two resulted from whooping-cough, one from scarlet fever, one from diphtheria, and one from "fever." These five deaths were equal to an annual rate of 0·7 per 1000, the zymotic death-rate during the same period being 1·5 in London and 2·0 in Edinburgh. The fatal cases of whooping-cough, which had been five, three, and three in the three preceding weeks, declined last week to two. The 131 deaths in Dublin last week included 24 of children under one year of age and 41 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons slightly exceeded the numbers recorded in the preceding week. Four inquest cases and one death from violence were registered; and 47, or more than one-third, of the deaths occurred in public institutions. The causes of three, or more than 2 per cent., of the deaths in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE

THE following appointments are notified:—Surgeons: A. J. Wernet, and H. C. Woodyatt to the *Pembroke*; D. V. Lowndes and A. R. Thomas to the *Wildfire*; C. E. C. Stamford, E. F. Ellis, and P F. Alderson to the *Duke of Wellington*; T. F. O'Keefe, G. C. C. Ross, and J. Thornhill to the *Vivid*; M. Cameron to the *Harrier*; and R. D. Jameson to the *Northampton* for the *Cleopatra*.

ROYAL ARMY MEDICAL CORPS.

Captain H. A. Hinge has joined at Aldershot for duty. Lieutenant-Colonel G. Coutts has been posted to the Western District. Lieutenant-Colonel W. Finlay, retired list, has been appointed to the medical charge of the troops at Jersey.

SOUTH AFRICAN WAR NOTES.

The following officers are on passage home:—Major H. T. Knaggs, R.A.M.C., and Civil-Surgeon E. C. Taylor.

The following officers have been discharged from hospital to duty:—Lieutenant-Colonel R. H. Nicholson, R.A.M.C., Lieutenant-Colonel W. P. Squire, R.A.M.C., Lieutenant G. G. Delap, R.A.M.C., Civil-Surgeon Glasse, and Civil-Surgeon John Alexander Black.

The wounded and sick who have passed through the Victoria Hospital in Rhodesia have, in token of their gratitude for the care bestowed upon them, subscribed £43 for a piano, to be presented to the hospital, for the use of the nurses.

Civil-Surgeon Wilbond is reported out of danger (June 28th).

The *Times* publishes the following:— "'In Arduis Fidelis' writes from No. 10 General Hospital, Norval's Point, under date May 15th: 'The Volunteer R.A.M.C., who have been out here 15 and 16 months doing constant work without any rest at all, are still in South Africa, and they cannot get the slightest attention paid to their repeated question as to the probable date of their return.'"

AFFAIRS IN SOUTH AFRICA.

The information from the seat of war in South Africa continues, and it seems likely to continue for some time yet, to be of much the same nature as it has been. The recrudescence of activity on the part of the Boers, however disappointing, does not appear likely to prove very important; their raiding attacks are, as a rule, futile as regards any advantage to themselves, and their chronic losses in the way of cattle, food, forage, and munitions of war must be "totalling up" to a very large aggregate. Fortunately, this country has command of the seaboard, and, costly as the process is proving, the supplies for the British are practically unlimited. We are not going into the question of the "concentration camps." Everybody regrets the sickness, the misery, and the suffering which these have entailed. But if the Boer families, forsaken by their natural protectors in order to fight against us, had been left to their fate they would have perished miserably on the veldt. As it was, every Boer farm formed also a little arsenal and commissariat depôt and a source of secret information to be used against us. No other course seemed to be open to us than to move the Boer families into camps. Their numbers, their ignorance and neglect of all sanitary precautions, and the raids made by the Boers on the railway which was the source of their and our own supplies, made the undertaking of accommodating, feeding, and providing for so large a number of people a very formidable one and full of difficulties. Would any other nation have made the attempt to succour and to do the best for them?

THE REORGANISATION OF THE ARMY MEDICAL SERVICE.

The committee of experts to consider a scheme which has been drawn up by Mr. Brodrick for the future organisation of the Army Medical Service will consist of the following members:—Dr. Howard H. Tooth, C.M.G., representing St. Bartholomew's Hospital; Mr. George H. Makins, C.B., St. Thomas's Hospital; Mr. Alfred D. Fripp, C.B., Guy's Hospital; Sir F. Treves, K.C.V.O., C.B., London Hospital; Dr. Alexander Ogston, Scotland; Lieutenant-Colonel A. H. Keogh, C.B., R.A.M.C., Ireland; Dr. E. C. Perry, Senate of London University; Surgeon-General W. R. Hooper, C.S.I., I.M.S., President of the Medical Board, India Office; and two officers to represent the army, who will be named by the Commander-in-Chief. The secretary will be Major H. E. R. James, R.A.M.C., F.R.C.S. Eng., and Mr. Brodrick will take the chair of the committee.

We understand that the hospital ship *Maine*, which is to be fitted out for further service under the Admiralty, will have a merchant crew with a naval medical staff.

Correspondence.

"Audi alteram partem"

"UNBOILED v BOILED MILK."

To the Editors of THE LANCET

SIRS,—Will you allow me to reply *briefly to Dr Clement* Dukes's letter which appeared in THE LANCET of June 29th on the subject of boiled and unboiled milk? Dr Clement Dukes is a great authority on pediatrics and the question he raises is a very important one in prophylactic hygiene

During the last 10 years in Paris we have been studying the nutritive value of sterilised milk in making large distributions of milk—from 50 to 150 litres a day—in special consultations called *gouttes de lait* (drops of milk), young *infants being brought to be inspected by the* doctor once or twice a week They are weighed, their weight is noted on a card, and the mothers receive advice as to the giving of milk, *its dilution (if required), and the* different quantities to give [illegible] and its weight. In these [illegible] ground of experience and [illegible] infants, some, following M [illegible] they sterilise in Paris with Soxhlet's system, others, like myself at the Dispensaire de Belleville, use milk sterilised at 115° C, by industrial proceedings in large establishments in Normandy This milk *is brought to Paris in bottles* of half a litre and less, and can be kept several days until it is used without its sterilisation being effected

In these conditions we have given this milk to a number of *infants* carefully looked after and we have noted neither rickets nor infantile scurvy with either method of sterilisation adopted by us In five years I have had about 200,000 litres of industrially sterilised milk distributed to over 1000 *infants and I have never observed a single case of Barlow's* disease Ricket [illegible] children whom [illegible] sterilised milk. [illegible] are anæmia with paleness of the teguments and habitual constipation, but it is difficult to fix what share of this is due to the artificial feeding and what to unhealthy dwelling conditions in the poorer classes, for these troubles are more common in winter than in summer. Infantile scurvy is very rare in France Ten cases have been collected and published in [illegible] of these can be [illegible] So it [illegible] an its ste[illegible] milks artificially made up in special laboratories by the method of Morgan Rotch seem to us most dangerous food to give to young infants even if well sterilised But simply to sterilise natural milk, even at 115 C, does not in my opinion, make it lose its nutritive qualities as Dr Clement Dukes seems to think. We have brought up a large number of healthy [illegible] with sterilised milk The tra[illegible] as perfect as in the case [illegible] are nevertheless very satisfactory in general.

In early infancy the presence of pathogenic germs, tuberculous, typhic, diphtheritic bacilli *is not alone to* be feared The possibility of these infections is more to be considered in schools, colleges, &c, than in our infants' department Saprophytes of all kinds that pollute milk and *make it ferment in a very complicated way in altering* either the lactose or the casein, &c., are particularly dangerous for the digestive organs of very young children We see this only [illegible] summer months when the rate [illegible] or 300 a week; the children of the poorer classes receive milk purchased at the lowest possible price at the nearest dairy or from sellers who go from door to door It is generally fermented often adulterated, water is added, &c. Fraud is practised on milk more than on any other product, and can be but with difficulty repressed in *large towns. That is why in Paris* I give the *preference* to industrially sterilised milk that reaches us in hermetically closed bottles sealed with paraffined corks which cannot be tampered with. In large centres of population where the carriage of milk is slow and complicated, the milk passing through so many hands before reaching the consumer, we must first of all manage to give our infants a *pure*, unfermented, unsophisticated milk, and the simplest way to procure this is to have recourse to a good industrial brand of milk sterilised in the country, just as one orders a well-known brand of champagne which one knows to deserve its reputation In this way we generally preserve infants from summer diarrhœa, and when cases do occur they are almost always benign

In the country, when one can obtain good fresh milk, being certain of the honesty of the provider and of the healthy condition of his cows, there is no fear of pathogenic germs, and if the milk is *newly drawn there can be no fermentation*, in these conditions it can safely be given to young infants But if we reflect we come to the conclusion that unless one has a farm and cows of one's own and under personal supervision it is not safe to give one's confidence (and that not for a day but for a whole year and more) to any dealer who may have his shortcomings

The boiling and sterilisation of milk are but a *pis aller* it is true, but neither has the inconveniences or the dangers *attributed* to it, which *one would* be *more* justified in attributing to food mixtures and modified milks The milk problem is an extremely complicated question and one which we can only hope to elucidate by long *and patient researches and* with a suitable *field of observation* at our disposal The same milk that will be poisonous for very young infants may not, or may scarcely, affect children from five or six to 12 years of age, who already resemble *adults in a certain degree At that age the gastro-intestinal* ferments have probably a greater bactericidal power than in newly-born children whose gastro intestinal functions are as superactive as they are unstable The results of our experience in Paris in our "drops of milk" forces us to adopt sterilised milk as an absolute necessity if we wish to preserve infants from serious gastro intestinal disorders and thus to diminish the rate of infantile mortality

I am, Sirs, yours faithfully,

DR G VARIOT,

Médecin de l Hôpital des Enfants Malades, Paris

July 2nd, 1901

To the Editors of THE LANCET

SIRS,—I cannot believe that Dr Clement Dukes can have inspected many farm dairies or he would never advocate the use of unboiled milk, whatever is lost in the nutritive value of the milk by boiling The risk to children is far too great, and until some stringent laws are passed and enforced requiring that every dairy farm shall be conducted under definite approved sanitary rules and officially inspected I think the profession should advise that all milk used as food for infants should be first boiled or sterilised I believe that THE LANCET has more than once advocated this course I quite agree with Dr Dukes that if you are absolutely certain of the supply of milk raw milk is far better than boiled milk as a food for children, but I cannot agree with him from very ample practical experience "that the nutritive value of milk is very largely diminished by boiling" It is, as I have already agreed, diminished but not *very largely* I have seen many cases of very weakly children reared on milk which has always been sterilised under my direction and the results have been very good Of course, I am speaking about London Dr Dukes from his remarks concerning his practical experience, is speaking about the Rugby district where I have always heard there is an excellent supply of pure milk, and doubtless Dr Dukes's ever-watchful eye has *made* the dairy-keepers very careful as to their sanitary arrangements for many a mile round But for the profession to advise the use of raw milk for children in London and other large towns, with the risk of its being contaminated by *the bacillus* tuberculosis the bacillus typhosus, the bacillus diphtheriæ, or the bacillus coli communis, I confess in my opinion would be nearly criminal whatever is lost in the nutritive value We can supply the deficiency

I am, Sirs, yours faithfully,

THOMAS DUTTON, M D Durh

Manchester-square W June 28th 1901

To the Editors of THE LANCET

SIRS,—Feeling strongly that the conclusion arrived at by Dr Dukes, and expressed in his letter which appears in THE LANCET of June 29th p 1859, would, if uncontradicted, do an immense amount of harm, and as also the "facts" he relies on are not "facts" in the opinion of many well qualified to judge, I venture to ask you to insert this letter

If there is any one "fact" in the whole province of medicine which has become accepted on the experience of many years and in every part country more than any other, it is the "fact" that milk is capable of carrying and disseminating disease. This has been proved up to the hilt in the investigation of numberless epidemics by the most eminent men in our profession, and the attention which has been called to the subject by them has resulted in an enormous saving of life and suffering.

Dr. Dukes asks the profession to cast away its universal experience in favour of the experience of one man accustomed only to the care of the boys in a very high-class country school in which the hygienic and other surroundings are perfect and the boys themselves of the strongest physique. I would wish to point also that this dangerous and retrograde view is advanced in the face of the recent experience at Glasgow and other large towns, where the mortality of the children has largely decreased by the sale of sterilised milk by the municipalities. Dr. Dukes's statement that "the nutritive value of milk is largely reduced by boiling" is entirely unproved, and "that this is true also of sterilised milk" is entirely the reverse of the fact. The nutritive value of milk is entirely unchanged either by boiling in a water-jacket, as in the ordinary milk-boilers now almost universally used, or by sterilisation by heat.

Of course, burnt milk heated carelessly in a plain saucepan is not only unpleasant but is innutritious, but this is no reason why people should be asked to give up a harmless precaution which has been proved over and over again to be most valuable in preventing infectious disease when it is absolutely impossible to know the source of the milk-supply or to keep such source, even if known, under supervision. I have myself traced three cases of enteric fever to the consumption of unboiled milk at country railway stations, and in one epidemic of scarlet fever to my knowledge every house attacked received its milk-supply from one dairy, and at that dairy it was found that the cows were milked by a man who had three cases of scarlet fever in his cottage.

I am, Sirs, yours faithfully,
ALBERT BENTHALL, F.R.C.P. Edin.
Cockspur-street, Pall-Mall, June 29th, 1901.

To the Editors of THE LANCET.

SIRS,—Dr. Clement Dukes has raised a question of the greatest practical importance and his authority lends especial weight to his opinion. As one whose duties include the advising of diet for a large number of infants and young children in a crowded district in London and who invariably orders milk to be boiled I should like to ask: 1. Whether the gradual exposure of milk to a temperature of 212° F.—i.e., short of its own boiling-point—injures its nutritive properties materially? 2. Whether Dr. Dukes's happy experience of freedom from epidemic disease at the school for which he acts may not be due in large part to the power of inspection and control of the milk-supply which is possible in such an institution? 3. Whether, in dealing with a crowded urban community where the milk-supply is various and cannot be efficiently controlled, boiling the milk or heating it to near boiling-point does not still offer the least of two evils and save more lives by the prevention of tubercle and of the acute specific fevers than are lost by the injury to the nutritive value of the milk?

I am, Sirs, yours faithfully,
Finsbury-square, E.C., June 28th, 1901. R. HINGSTON FOX.

To the Editors of THE LANCET.

SIRS,—It is refreshing to find such men as Dr. Vivian Poore and Dr. Clement Dukes protesting against the habitual use of boiled milk, for it is high time an outcry should be raised against such a detrimental practice. For myself I have persistently denounced the boiling and sterilising of milk and can only say I have never had cause to regret having done so. If cows really spread tuberculous disease to the extent which some medical men assert then I would say, since there has been no inspection of cows till of late years it is a wonder there is a single family in Great Britain free from this disease. Years ago it was said that consumption had greatly diminished in the fen country owing to increased drainage, but how did the decline take place if it was daily being disseminated by the ingestion of tuberculous milk? If tuberculous disease has increased so much of late years, then such prophylactics as purer air (provided as it has been by open spaces and diminished overcrowding), better food, and better clothing have proved more or less failures, and, moreover, little can be said for the open-air treatment of consumption, since even the cows have been fed upon fresher and more natural food, and also less confined in close, pent-up sheds. What we really want is, as Dr. Clement Dukes says, more complete and efficient inspection all the way round.

I am, Sirs, yours faithfully,
Bexhill. F. P. ATKINSON.

To the Editors of THE LANCET.

SIRS,—Dr. Clement Dukes has raised a very important question in his letter on this subject in THE LANCET of June 29th, p. 1859, and I am glad he has done so because, doubtless in common with many others, I have had growing doubts as to the wisdom of advising parents to use sterilised milk—doubts which have partly arisen from experiencing some of the evil results to which Dr. Dukes alludes. I do not write with any idea of combating what he has said, but only in the hope that the subject may not be allowed to drop without the discussion it merits. Perhaps the question is mainly of importance as affecting the feeding of infants. Dr. Dukes's position is that in protecting them from certain possible dangers we are subjecting them to other positive evils. The main danger from which the profession has been anxious to protect them in advising the boiling of milk is tuberculosis, for it is the one most constantly present, and apart from this our advice to parents would possibly have been to boil milk only during the prevalence of epidemics of scarlet fever, diphtheria, &c. That this danger of tuberculosis is very generally present is shown by various investigations which have been made—e.g., one made by the late Professor Kanthack and Dr. Sladen into the milk supplied to the various colleges of Cambridge, in which they found tubercle bacilli present in more than 50 per cent. of the different supplies.

On the other hand, the question arises whether, though sterilised milk has been very largely used during the last few years, the cases of evil resulting therefrom have been really numerous; or, in other words, whether the danger which results from boiling milk, though undoubtedly a possible one, is as certain or general as, I gather, Dr. Dukes believes, or sufficiently so to make us cease to advise the boiling of milk. But even supposing that it is, a further question arises, and that is whether we may not avoid this danger in some other way than by ceasing to sterilise milk—as, for instance, by an addition to the milk after boiling which shall make up for the deleterious change, whatever it is, which the boiling has caused. And this is surely a field for profitable research; for at present, so far as my knowledge goes, it is uncertain what this change is. The danger to seamen arising from the absence of fresh food has been met otherwise than by doing away with preserved food.

Though, as I have said, the question is chiefly of importance in infant feeding, it is also worth considering whether the same danger threatens older children, in whose diet milk takes a subsidiary place; or whether, when they are of an age to take a mixed diet with plenty of other fresh food we may not protect them from the dangers of contaminated milk without substituting dangers in other directions.

I am, Sirs, yours faithfully,
Cambridge, June 29th, 1901. ARNOLD C. INGLE.

To the Editors of THE LANCET.

SIRS,—I have only just read Dr. Clement Dukes's letter on boiled milk, and so strongly do I feel on the matter that I feel it a genuine duty to our infant and invalid population to add whatever small weight of influence I may possess into the same scale with Dr. Dukes. My out-patient department at the London Hospital consists to a very considerable extent of babies, and it is simply heartrending to see the numbers of such helpless creatures who are made peevish, fretful, and even seriously ill by the pernicious effects of boiled milk on their nutrition. I heartily and absolutely agree with Dr Dukes that it is in more stringent precautions against th *entrance* of evil-minded microbes that we must find our bes safeguards against the spread of infection by milk, and no in the destruction of them after they have gained entranc by processes which most certainly reduce by a large percentage the nutritive qualities of the article.

I am, Sirs, yours faithfully,
FRED J. SMITH,
July 3rd, 1901. Physician to the London Hospital.

To the Editors of THE LANCET.

SIRS,—May I ask Dr. Clement Dukes to give more fully his grounds for the statements made in his letter to you las week: (1) that the nutritive value of milk is largely diminished by boiling; and (2) that this is also true of sterilised milk? In regard to the case he quotes he does not say whether the "anti-scorbutic food" which caused the child's recovery from scurvy consisted *solely* of unboiled milk or whether anything else, which might have been at any rate partially responsible for the recovery, was included. Again, the absence of tuberculous disease from infection by a milk-supply, which is probably from a carefully selected source, in the boys of a "large public school" where hygienic conditions are so good and outdoor life so universal, is no very strong argument against its transmission to the less fortunately circumstanced children of our large towns.

I am, Sirs, yours faithfully,

June 23th, 1901. M.B., CH.B.

THE CONTAMINATION OF POST-OFFICES.

To the Editors of THE LANCET.

SIRS,—As Parliamentary secretary to the Postal Telegraph Clerks' Association I shall be grateful if you can give me a little space for the purpose of explaining the motives which prompted the members of my organisation to ask Sir W. Foster to take charge of our clause in the new Factory Bill. We have no desire to attack the medical department of the Post Office, but we are anxious to secure sanitary conditions in the telegraph offices The tone of the annotation in THE LANCET of June 29th seemed to convey the impression that you concurred in the view that improvement was necessary, but that the present system of inspection is sufficient to meet the needs of the case. But the question that arises is, Has the present system succeeded? Let the Inter-Departmental Committee (Tweedmouth) answer. It made inquiries at 182 offices and as a result admitted that 69 were in an insanitary condition. Defective ventilation, bad drains, and urinals and water-closets near dining-rooms were the main charges against the Post Office and they were admitted. If the system was satisfactory how came it that a committee of inquiry such as this could report, "Much still requires to be accomplished before the post-office buildings of the country will be placed in a univers[illegible]"

Two [illegible] gation [illegible] London, had complained of insanitary conditions for a long period, but they appealed to deaf ears. When, however, the Tweedmouth Committee visited the building and Dr. W. H. Corfield was asked to make a special report the building was condemned as "overcrowded, incommodious, and insanitary." The staff of the Chief Telegraph Office also complained of insanitation, unsafe exits, and overcrowded dining-rooms. Again the official reports denied the existence of the grievances. After much stir in the public press, many questions in Parliament, and a personal inspection by the Duke of Norfolk, it was found that most of the charges were [illegible] great outlay were made.

[illegible] laid down several "canons" [illegible] Among others were: a due amount of cubic air-space; that all outside doors should open into porches or other like arrangement and never directly into the rooms where the staff are at work; that heating should be by hot-water pipes or hot air; that lavatory accommod[illegible] they should never [illegible] other room; and t[illegible] the work of a post-office the walls, &c., of all offices should be more frequently washed and cleansed than at present is considered necessary.

My association collects facts regarding telegraph offices only, but Sir W. Foster and Sir C. Dilke have been supplied with 50 foolscap sheets of typewriting containing details of cases in offices throughout the kingdom where practically nothing has been done to give effect to these "canons." I am aware that the fault is said to rest with the Office of Works, and it was stated in 1897 that it should be "held to be imperative on the Office of Works to carry out all the demands concerning any local insanitary condition made by the *medical* officers through the correct departmental channel." Mr. Balfour assured the House of Commons on June 7th that every one of the Tweedmouth recommendations had been carried out, and if he is right then the Office of Works naturally obeys this "imperative" injunction.

But telegraph clerks cannot penetrate into the official secrets. We know that insanitation exists and we want it remedied. *At present we have but two methods:* (1) *by* means of a petition; and (2) by drawing Parliamentary attention to the case. Both are cumbersome and unsatisfactory and are a source of constant friction between the supervisory officials and the ordinary staff. We also know that new post-office buildings are not constructed with a view towards studying the health of the workers. Only last year Dr. Ransom of Nottingham suggested that insurance companies before insuring the lives of post-office employés should insist upon some reform, and his remarks were based upon his knowledge of the unsatisfactory condition of the new Nottingham post-office. I cannot trespass further upon your valuable space. But I wish to say this: what telegraphists desire is that the sanitation of the offices in which they work should be placed on a proper footing. It is too much to hope that the English Government will attempt to follow the example of the French administration, but as we have so often failed to secure reform by appealing to the authorities we must now help ourselves.

The Factory Bill gives us the opportunity and we *shall* try our utmost to secure some concession. Failing that, on each occasion the vote for Government buildings is taken in the Commons we shall make a fight. The only difficulty that exists is that a post-office is neither a factory nor a shop and the Government may escape by means of a legal quibble.

I am, Sirs, yours faithfully,

S. W. BELDERSON.

Grantham-road, London, S.W., June 29th, 1901.

"LEGISLATION AGAINST NATIONAL INTEMPERANCE."

To the Editors of THE LANCET.

SIRS,—Dr. Archdall Reid seems to me to be much too dogmatic in his statements. In discussing a question which is so far from being decided as that of the heredity of acquired characters I think that it is the part of a wise man to state his conclusions as probably or apparently true, rather *than to make positive statements which may be upset by fresh* evidence as soon as they have been made. Dr. Reid says that there is no more reason for supposing that muscle or liver or any other of the somatic cells are concerned in reproduction than for supposing that germ cells are concerned in the production of motion or of bile. The argument does not touch the problem. The question is not whether somatic cells are concerned in reproduction, but whether changes in the somatic cells may affect the powers of development or, to use a convenient term, the determinants, of the reproductive cells. Now, it seems to me that if one says that there is no more reason for supposing that the somatic cells can affect the properties of the germ cells than for supposing that the germ cells can affect the properties of the somatic cells, it may be replied, "Just so, but there is very obvious evidence that the germ cells, or at any rate the reproductive organs, can affect most profoundly the development of the somatic cells." I refer, of course, to the well-known but most remarkable effects of castration. If the somatic cells were absolutely independent of the germ cells, I fail to see why the antlers should not develop normally in a castrated stag or why the larynx should remain in the puerile condition in a castrated man

With regard to alcohol, I could scarcely venture to discuss the evidence in detail, but *Dr Reid's arguments do not seem* to me convincing. The idea of alcohol causing extinction by injuring the germs seems to me again beside the question. The almost universal use of alcohol in the majority of human races proves that in moderation it does not necessarily produce evil effects. The *excessive* consumption of alcohol is known to produce neurotic degeneration in the individual. My own conclusion is that excessive indulgence in any person necessarily causes an inordinate appetite or craving for alcohol, and that this craving, with the neurosis underlying it, is often strongly inherited. To my mind the neurosis is an acquired character and the inheritance beyond doubt. I know of instances from my own observation. *When the craving is indulged the* nervous degeneration becomes greater in successive generations, resulting in *insanity, paralysis, idiocy, or cerebral* defect of some kind. Dr Archdall Reid, if he wishes to convince his opponents, should prove that the children of habitual drunkards are normally developed both mentally and physically.

Another consideration of great importance which is generally overlooked is the following. Intemperate habits are very often acquired, or developed, rather late in life, after the victims of them have produced all their children. The children cannot in such cases inherit any of the effects of such habits on the constitution. It is the general experience of breeders of animals that the offspring inherit characters more strongly when the parents are more mature, that is to say, characters which continue to develop until an advanced period of life, e.g., the peculiarities of the carrier pigeon. The mental powers in man are an example of the same kind. They continue to develop long after the time at which most men beget their children, and there is some reason to believe that younger sons generally inherit more brain-power as well as less property. There is also some reason to believe that children produced of aged parents are, in a sense, born old. Such facts, if they are facts, cannot be explained on the assumption that the germ-cells are independent of the history of the soma, and in investigating the inheritance of degeneration due to alcoholism the duration of the alcoholism in the parents *before* the generation of the children must be ascertained. I am, Sirs, yours faithfully,

June 21st, 1901. J. T. CUNNINGHAM.

To the Editors of THE LANCET.

SIRS,—To judge by Dr. Andrew Wilson's letter in THE LANCET of June 29th, p. 1861, I do not seem to have made my position as "clear" as he asserts. I am sure I do not know whether "the germ-plasm is utterly independent of the body-plasm," or "whether the great divergence between germ and soma contended for by Galton (?) and Weismann is a reality." I know absolutely nothing about all that, and, notwithstanding the vast flood of mystical chatter indulged in by various eminent biologists, I am equally sure that nobody else knows more. But I do positively know (1) that a child (for instance) is derived from a single cell of each parent and (2) that the soma (i.e., the other cells) of each man acquires millions of traits. It seems to me incredible that each of these millions of acquirements can so affect the germ that every particular acquirement tends to be reproduced by the child. In other words, the assumption that the offspring of the germ cell tend to reproduce the acquirements of the other cells seems to me as improbable as the assumption that the offspring of Brown tend to reproduce the acquirements of Jones and Robinson. I know, moreover, that for 20 years search has been made for indubitable instances of transmission without success. When, therefore, the transmission is alleged I ask for proof. Dr. Wilson, in reply, refers me to the works of Darwin, Herbert Spencer, Eimer, and others—to this gentleman and that. He adopts an impossible method of controversy. I cannot review the works of Spencer, for instance, in the correspondence columns of THE LANCET. I am prepared, however, to make Dr. Wilson a reasonable offer. Let him describe (giving the necessary details) any instance of transmission alleged by the gentlemen he has named and I will undertake to demonstrate the fallacy. Indeed, so strong do I feel my position to be that I willingly grant him the whole literature of the subject to delve in.

The last sentence of his letter is characteristic. In effect he asserts that nobody has proved that acquired traits are *not* transmitted. I quite agree, and I may add that nobody will ever prove it, but only because no one can prove a negative. Suppose, for instance, I stated that at three minutes past midnight on Nov. 10th, 1900, a dragon sat and curled his whiskers on the cross of St. Paul's could anyone disprove the assertion? Could Dr. Wilson? Certainly not. He would merely say that my assertion was incredible and ask *me* for evidence. I ask him for evidence. The onus of proof rests with him.—I am, Sirs, yours faithfully,

Southsea, July 1st, 1901. G. ARCHDALL REID.

"PUERPERAL FEVER TREATED WITH ANTI-STREPTOCOCCIC SERUM."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of June 29th, p. 1824, I read notes of a case which appears under the heading: "A Case of Puerperal Fever treated with Anti-streptococcic Serum; Death." I think this heading is distinctly misleading. From May 1st the patient is passing through an intensely septic process with repeated rigors, delirium, incontinence of urine (which was albuminous), and thrombosis of both legs and left arm. The patient's condition became so critical that strychnine and brandy were necessary on *May 18th. Then,* on *May 19th, anti-streptococcic serum was used for the first time.* I think that it would have been wise to have stated that the serum was first employed on the nineteenth day after the manifestation of septicæmia. Moreover, one would like to know whether: (1) the case had been proved to be one of pure streptococcic infection by bacteriological and microscopical examination; and (2) what was the nature of the nurse's infection? My personal experience of anti-streptococcic serum is that if it be used early and in sufficient dosage in suitable cases—i.e., in cases proved to be of streptococcic origin—it is as valuable a therapeutic agent as anti-diphtheritic serum.

I am, Sirs, yours faithfully,

Bedford, June 30th, 1901. S. J. ROSS.

ALFRED HUGHES MEMORIAL AT KING'S COLLEGE, LONDON.

To the Editors of THE LANCET.

SIRS,—A movement has been set on foot to establish a memorial to the late Professor Hughes at King's College. It has been felt that his memory should be perpetuated in London as well as in Wales, for the last years of his life were spent with characteristic energy among London students. His anatomical collection has, in accordance with his expressed wish, been presented to King's College by Mrs. Hughes and will bear his name. It is hoped that the fund now being collected will enable us to erect a memorial tablet in the anatomical museum or college chapel and also to found a scholarship or medal in anatomy to be awarded annually and to be named after our late colleague. With this object in view a large number of circulars have been posted to members of the medical profession, prominent anatomists, and others. Already a considerable number of subscriptions have been sent in. These include £5 from Lord Lister, £5 from the Hon. W. F. D. Smith, M.P. (treasurer of King's College), £2 2*s.* from the Archbishop of York, and a number of others, principally from members of the Council, the staff, and the students of King's College. The object of this letter is to make the fund still more widely known. There are doubtless many of Professor Hughes's friends and old students whom it is difficult to reach in other ways who would like to show their appreciation of his worth by sending donations to the fund. A full list of subscribers will be published later. Contributions should be sent to me.

I am, Sirs, yours faithfully,

W. D. HALLIBURTON.

King's College, Strand, June 30th, 1901.

THE TREATMENT OF DYSENTERY AT SPA BY CHALYBEATE WATERS, &c.

To the Editors of THE LANCET.

SIRS,—I think the following case of sufficient importance at the present juncture to warrant publication. Captain ——, aged 27 years, good antecedents, consulted me at Spa on June 9th, having been invalided home from the Cape after dysentery. He had a relapse on the way home, and when first seen was passing from eight to ten bloody stools per diem, with inability to leave his hotel without previously taking 10 drops of chlorodyne, &c. I put him on a course of our iron water and douches and an internal antiseptic treatment. The result has been most satisfactory. In 16 days he has put on eight pounds weight and is now, since eight days, passing formed stools without blood and has ceased using chlorodyne. I am, Sirs, yours faithfully,

DR. A. CAFFERATA.

Avenue du Marteau, Spa, June 28th, 1901.

EQUINE VARIOLA—HORSE POX.

To the Editors of THE LANCET.

SIRS,—During the last few weeks I have had five or six cases of the above disease in the human being accidentally inoculated from the horse, but as I do not remember ever seeing any note of similar cases I thought it might be of interest to record it. The subjects have all been stable lads employed at racing stables, and the disease has generally been inoculated into the hand or arm while drenching or balling a horse. In one case, however, the upper eyelid was the seat of inoculation. The phenomena have been far more acute and of shorter duration than in *vaccinia.*

I am informed that several years ago a number of cases were seen here in which the symptoms were so acute that the disease was at *first diagnosed as anthrax*

I am, Sirs, yours faithfully,

Newmarket, July 2nd, 1901 ERNEST CROMPTON, M R C S

"SIMULATION OF BERI-BERI"

To the Editors of THE LANCET

SIRS,—*Apropos* of your annotation on simulation of beri-beri in THE LANCET of May 25th, p 1483, this method of producing an œdema of the feet is well known to Indian prisoners I remember such an "outbreak" some years ago when it was found that the œdema was produced by a needle-and-thread soaked in lime —I am, Sirs, yours faithfully,

Bengal, June 9th, 1901 W J B

THE DIFFERENCE BETWEEN THE GENERAL MEDICAL COUNCIL AND THE CONJOINT BOARD.

To the Editors of THE LANCET

SIRS,—Having been forced to take great interest in the preliminary scientific education of medical students during the last two years my experiences and conclusions may interest your readers

First, the experiences In the autumn of 1899 I applied at the offices of the General Medical Council for information as to where the first year of studentship might be passed, and was given the list of schools recognised by the Conjoint Board as being a reliable guide In January, 1900, my eldest son, who had entered at one of these schools, was told when he applied to register that the list of the Conjoint Board was no longer recognised by the Council *and that his case must be considered specially* Eventually, after a period of suspense, his time was recognised. In July, 1900, I [illegible] General Medical Council for a [illegible] as another son had matriculated [illegible] him to lodgings in London when he was barely 17 The Registrar wrote· "The question of the approval of these institutions is still under consideration, each case is meanwhile considered on its merits" The question remained under consideration for the whole of 1900, no doubt to the great inconvenience of many others besides myself and my son I fixed on a public school recognised by the Conjoint Board which had four boys in its "science sixth," who had passed the Preliminary Scientific London, and others preparing for it, and I inquired of the Registrar whether my second son's time would be recognised if it was spent there His answer was to the effect that the Council objected to that class of school, but at the same time he recommended a university college in the same town at which my son would have none of the great advantages of school life—e g, games, supervision, &c Eventually I had to enter him at a London hospital (paying £50) to enable him to register, and send him to an unrecognised school besides, as I wanted him to pass [illegible] unnecessary delay If you [illegible]onished to find how many of the London hospitals cannot be relied upon to pass their candidates for that examination Some are safe on the zoological side but cannot teach students the necessary chemistry and physics; with others it is the opposite, and probably there are some that can teach both, but the unrecognised school does best.

My conclusions are that the General Medical Council has not given due consideration to the convenience of medical students and their guardians Full notice of these alterations should have been made public and sent to the schools concerned (Two of the schools learned the news from me nine months after their tacit recognition by the Council had ceased) The year and a half of suspense has probably been a great inconvenience to many and there should be strong grounds to excuse it The final decision is likely to be very detrimental to students in future Firstly, by preventing the youth of 16 or 17 years of age who is anxious to press forward in the medical profession from spending the usual final year at school where he learns much that is good for him as monitor, leader in games, and such like to say nothing of the great physical advantages which school has over life in London lodgings These deprivations I regard as positively cruel towards the student and injurious to our profession, which depends on the good qualities of its members for the position which it holds *If the rising generation of medical* practitioners be forced into cheap lodgings in big cities at an early age we may safely foretell retrogression Secondly, in many cases the youth will have to forego a good system of education for an inferior one

The Conjoint Board may have been too free with its recognitions, but certainly the Council has not been free enough Surely all schools which can pass students for the Preliminary Scientific, London, regularly might be recognised by the Council, or, better still, students who pass the preliminary scientific or first professional examination of any licensing body might be accredited with having done the period of studentship allotted to preparation for it by medical schools Why should a system of protection through registration be afforded to the recognised medical schools and a few others when their education in elementary science is not always the best There is a general opinion that the great argument in favour of the five years' curriculum was that medical students had not enough practical work in their courses and that part of the fifth year at least was to be devoted to assisting physicians, surgeons, or general practitioners in hospital or outside Now that it is instituted we find students forced to spend at least a year at preliminary subjects and the same old want of real experience facing the newly-fledged licentiate though he has spent more time and more money in getting qualified than his father did (for all the hospitals have raised their fees) May the memory that, unlike his father, he spent much time and energy in hunting for the ovaries of earth-worms and the lymphatic hearts of frogs console him in his trouble over failure to put his first good private patient on a satisfactory diet. Is this elaborate training in elementary science really advisable? It is possible to give students too much of a good thing I am, Sirs, yours faithfully,

June 28th, 1901 MEDICUS ET PATER

BIRMINGHAM

(FROM OUR OWN CORRESPONDENT)

Birmingham and Midland Counties Branch of the British Medical Association

THE annual meeting of the Birmingham and Midland Counties Branch of the British Medical Association was held on June 13th at the Medical Institute The report of the council stated that the last year had been one of exceptional interest and activity In addition to the ordinary meetings two special meetings of the branch had been held, and the attendance had reached the high average of 65 per meeting, the extremes being 38 and 109 There had also been six special council meetings *One of the* special branch meetings and the greater part of one ordinary meeting were devoted to a discussion on the Coventry Provident Dispensary, and a resolution was passed expressing the opinion that no professional recognition should be given to the medical staff of that institution by members of the branch Forty new members had been elected during the session, and the present membership of the branch was 443 The report of the pathological and clinical section, and the report of the ethical committee were received, both of which evinced signs of much valuable work during the session The financial report showed a balance of £23 4*s* Various votes of thanks were passed Dr Malins was elected president and Mr J T. J Morrison and Dr T Stacey Wilson were elected honorary secretaries The members, with a distinguished representation of the City Council, the University and friends, dined together subsequently, the proceedings being characterised by enthusiasm and good feeling throughout

The University of Birmingham

The different faculties have had a busy time recently in conducting examinations for degrees of the new University The medical faculty has been exceptionally occupied by the large number of candidates Forty-one qualified medical men availed themselves of the opportunity of taking the final examination for the degrees of M B and Ch B, having been past students of the school Some 27 of these were successful The first degree congregation of the University is to be held in the Town Hall on July 6th when the Chancellor of the University, the Right Hon Joseph Chamberlain will confer degrees upon the candidates for graduation. The council of the University has confirmed a recommendation of the Senate: "That at the forthcoming degree congregation every member of the Senate be admitted to a Master's degree, professors in the faculties of arts to receive the M.A. degree, and professors in the faculties of science and medicine the M.Sc. degree." The appropriate academicals being worn by the staff of the University and by the candidates an imposing array will be presented at the ceremony which is expected to be largely attended. An important letter from the Chancellor of the University was presented to the City Council on June 18th, in which Mr. Chamberlain recited the value of the University and the necessity of spending large sums on buildings, machinery, and equipment. He alluded to the liberality of many contributors and munificent gifts from strangers which had resulted in a subscription list of more than £400,000, and then made an appeal to the authorities of the city in the first place and also to those of the neighbouring counties to make a grant in aid of maintenance from the funds which the legislature has placed at their disposal or which they are authorised to raise by rates. Precedents are given from other towns. It is shown that a rate of a halfpenny in the pound would provide an annual contribution of £5000, which would justify the council in proceeding immediately with the new departments. The council of the city is already represented by five of its members upon the governing body of the University—a sufficient guarantee of the disposal of such contributions. The proposal was referred by the City Council without discussion to the General Purposes Committee with instructions to report.

The Housing Question.

At a meeting of the City Council held on June 18th a recommendation of the Health Committee was brought forward with regard to a plan to build 621 workmen's dwellings upon land purchased for that purpose last year at Bordesley Green. An amendment was carried by two votes, after considerable and lengthened discussion, that the scheme should be referred to a special Housing Committee to be appointed in November next. The chairman of the Health Committee therefore withdrew the motion. A motion to instruct the General Purposes Committee to hold an investigation as to any lack of efficiency in the sanitary administration of the city in recent years was also rejected. Much attention is being given by various ladies to the question of the hour in this direction. Ministers of religion preached special "slum" sermons on June 30th, and endeavours are being made to excite public interest in so important a matter.

Illness of Mr. Jordan Lloyd.

I regret to announce the illness of Mr. Jordan Lloyd which occurred somewhat suddenly and culminated in an operation for appendicitis on June 27th. This was performed by his colleague, Mr. Bennett May, and I am glad to hear that the patient is progressing satisfactorily. Mr. Jordan Lloyd's many friends will join in congratulations and hope for his speedy recovery.

Hospital Saturday Fund.

The amount paid into the bank this year, so far, amounts to £14,499 odd; last year it was £13,681. The committee hope that there will be a great many more subscribers to the fund this year.

July 2nd.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Watered Butter: Special Machinery.

CASES are not infrequently brought forward where butter has been watered, and strong opinions have been expressed *pro* and *con*. The dealers say that a certain percentage of water is necessary, but no doubt this is often fraudulently exceeded. On June 20th the proprietor of some creameries in Devonshire was fined £5 and costs at the City Police-court, Manchester, for giving a false warranty as to butter sold to a Manchester dealer. In this case the defendant pleaded guilty, and his solicitor was instructed to say that during a great rush of business the workpeople had probably been careless, and that during the last three years between 200 and 300 analyses had been made without any adulteration being found. This may, perhaps, be a feasible excuse. Such a plea, however, would not apply to a case heard at Ashton on June 26th, when a retail dealer was fined £10 and special costs amounting to £3 11s. In this case Mr. Williams, the county analyst, said that the butter contained over 23 per cent. of water, "the largest quantity, with one exception, that he had ever found in the county of Lancashire." He added also that "the water had been intentionally and fraudulently put in the butter. Special machines were sold for this purpose and in this case the butter had been warranted from the dairy in Somersetshire to the retailer." The report, which ends with the quaint remark—"much interest was evinced in the case"—does not make it clear whether the manufacturer or the retailer had exercised this misapplied ingenuity. But if "special machines are sold for this purpose," the practice of forcing an excess of water into the butter must be a common one.

Manchester Royal Infirmary.

On June 24th a recommendation from the appointments committee of the infirmary that Mr. J. V. Stock be appointed resident medical officer for one year at a salary of £150 was confirmed by the Manchester Infirmary Board. The Chairman, Sir Forbes Adam, also announced the election of Mr. J. W. Smith to the office of honorary assistant surgeon to fill the vacancy caused by the appointment of Mr. Joseph Collier as an honorary surgeon.

Review of the Lancashire St. John Ambulance Corps.

The St. John Ambulance movement may be taken as w established in Manchester, for the eleventh annual revie and demonstration of the North-east Lancashire corps the brigade was held on the Manchester Athletic Club grou on June 22nd. There was a good muster from the vario towns in the division and a large attendance of spectato The weather, unfortunately, interfered a good deal with t proceedings, but the principal competitions were successful gone through. The Manchester corps retained the Moll cup won by them last year, Preston and Blackpool comi second and third. The nursing division wore the regul tion uniform of black dresses with white aprons and cap and took part in the march-past and bandaging exhibition The inspecting officer was Colonel C. W. B. Bowdler (com missioner), and there were also present Lieutenant-Colon C. J. Trimble (deputy commissioner, No. 4 District) an Mr. J. C. Derham (assistant commissioner, No. 4 District the last of whom was in command. In his address to t brigade the inspecting officer expressed satisfaction at t manner in which the ambulance drill had been done and sai that 806 men had gone from that division to serve in Sout Africa and that "letters from the front spoke in high term of the splendid work they had been able to do there." Th showed the excellence of the training received at home.

Preservatives in Milk.

A case in which a milk-dealer of Gorton had bee summoned the previous week "for selling milk not of th nature, substance, and quality of the article demanded," wa brought up again for judgment before Mr. Yates, K.C., th stipendiary magistrate at the Manchester City Police-court, o June 25th. It was of some importance, being taken as a te case. The analysis by Mr. Williams of some of the milk i question showed that formalin had been added to the milk For the defence it was contended that it was added as a pre servative and was necessary for its carriage, also tha the analyst's certificate was insufficient as it was onl qualitative. The magistrate was of opinion that formali was so volatile that the quantity in the milk coul not be accurately ascertained, but if wrong in this opinion h was satisfied from Mr. Williams's evidence that there was a least one part in 50,000 of the milk. He thought that it was impossible to contend that (unless very carefully used by a experienced person) it was not injurious to health. It was very pungent, and had to be carefully handled to avoid injury to the hands, and it was admitted that if used in too large quantities it retarded digestion. He was glad to be able to arrive at this conclusion, as he thought it would be a very dangerous thing if an unskilled milk-dealer were allowed to mix an ingredient like formalin with a food so universally used as milk. He found that this milk was not of the nature, substance, and quality demanded, and that formalin was not necessary for its preservation during carriage. As it was a test case 40*s*. only and costs were imposed, and five guineas for extra costs.

Pollution of the Ship Canal.

At a meeting of the Mersey and Irwell Joint Committees held in Manchester on July 1st the corporations of Manchester and Salford came in for some strictures, especially the former. The Medlock is in a much worse condition at Knott Mill than when it enters the city, principally from trade waste, brewery waste, and from the storm overflows of the corporation sewers. According to the report of the chief inspector (Mr. R. A. Tatton) these are very unsatisfactory and are often found to be working not only when there is no storm, but in the driest weather. Mr. Tatton's reports on the progress of their sewage works" are to be sent to each corporation and attention is to be drawn "to the rise year by year in the amount of organic impurity in the effluent." The chairman to the Consulting Sub-Committee said that the fact that the Manchester effluents had steadily grown worse might be accounted for by the effluents from a number of manufactories in the city being received by the sewers and possibly because there was an enormous decrease in the amount of the chemicals used. He thought that the Manchester Corporation should be told that as they had been so leniently treated they should do all they could to improve their tank effluent pending the completion of the bacteria beds. Another member said that they had tried the polite method for many years and he thought that it had lost its power. Both corporations were remarkably active in undertakings where they could see their way to a profit. He contrasted the expedition with which the Manchester Corporation tramways had been got to work with the method of dealing with the Ship Canal nuisance. One of the Manchester members said that the Rivers Committee of the corporation was doing "everything within the limits of human power," &c. It cannot be pleasant for the corporation to read such statements as are repeatedly made at the meetings of the Joint Committee, but the condition of the canal is bad enough to justify very strong language. As far down as Flixton, Lymm, and even Latchford its foulness seems to be no less than it was several years ago. The nuisance is so sickening and the stink is so unspeakably abominable that mere motives of humanity should urge the corporation to efforts a little greater than those considered by Mr. Brocklehurst to have reached the limits of human power, and no doubt this could be done.

Sandlebridge Colony for Epileptics

In addition to the provision for epileptics made by the joint committee of the boards of guardians of Manchester and Chorlton private benevolence is engaged on an important undertaking at Sandlebridge, near Alderley. About 130 acres of the Sandlebridge estate have been set aside and are being laid out as a colony for the treatment of epileptic patients. There will be accommodation at the outset for 200 patients. It is probable, however, that extensions will have to be made before long, as already the applications for admission from various parts of the country and from Ireland exceed that number. The sexes will be separated, there will be playgrounds and a school for children, and workshops and laundry for adults. The grounds have been planted with fruit trees and shrubs at a cost of some thousands of pounds. A few patients are to be received f [illegible] yment will be made for the inmates [illegible] the means of their friends. This [illegible] the visits paid by Dr. J. M. Rhodes and Alderman McDougall of the [illegible] uardians to various institutions for [illegible] eptics in Germany, France, and Belgium as a deputation from the Joint Asylums Committee. As a result of their reports and recommendations an influential committee was appointed to carry out a scheme for a colony and public subscriptions to the amount of between £7000 and £8000 were raised. Mr. B. W. Levy, the legatee of the late David Lewis, whose benefactions to Liverpool and Manchester deserve the gratitude of the community, was then appealed to. After investigation this gentleman decided to purchase the Sandlebridge estate of over 500 acres out of the Lewis Trust, and to provide the buildings and equipment at a cost of something like £120,000. But this most generous gift will not be sufficient for all purposes, and the committee has to raise from the public an endowment fund of at least £20,000, in addition to a certain sum in annual subscriptions. This is an admirable opportunity for the benevolent rich. It is expected that the colony will be ready for patients in about two years. At the last meeting of the Manchester Board of Guardians Alderman McDougall corrected an idea that had got abroad that the guardians would be able to send the epileptics from the workhouse to the Sandlebridge Hospital, which was never intended, as he delicately puts it, "for the guardians' patients."

July 2nd.

WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

Ratepayers' Associations.

THE avowed purpose of the ratepayers' associations which in recent years have been established in many towns is to keep down the rates in the particular districts concerned and they are thus in a sense antagonistic to sanitary reforms for which some expenditure is usually required. An exception is to be found at Dinas Powis, a village in the Llandaff rural district which adjoins, and is almost a suburb of, the town of Barry. The necessity for taking some action to improve the sanitary condition of the village was discussed at the last meeting of the sanitary committee of the Glamorgan County Council and a report has now been issued by the local ratepayers' association stating in considerable detail the actual conditions which are to be found. This report can hardly be pleasant reading to the district council, the members of which must feel that they have neglected the duty cast upon them by the Public Health Act, 1875, to inform themselves of the existence of any conditions which are inimical to the health of the inhabitants of their district. Information is given in the report of the association with regard to 277 of the 310 houses in the village. As there is no sewer a brook takes the overflow from 129 cesspools. In many other houses there are privy middens which are seldom emptied and in several instances the contents of cesspools and privies have to be carried through the living rooms of the houses to which they are attached. In his last annual report the medical officer of health drew the attention of the council to the condition of the village and pointed out the manner in which reforms could be effected.

Bristol Cottage Homes.

The Bristol Board of Guardians have 200 children living in 16 scattered homes and are proposing to establish at Downend a colony of cottage homes for the accommodation of 204 children. The scheme, for which plans were approved on June 28th, provides for the erection of 14 semi-detached houses each to accommodate 12 children, a convalescent home for 36 children, a large hall, and a lodge. Nine local architects had been invited to submit competitive designs and their estimates for carrying out the works indicated above varied from £14,165 to £23,380. The guardians decided to carry out the plans of the architect whose estimate was the lowest.

Bristol Hospital for Sick Children and Women.

The four days' bazaar which was recently held in Bristol for the purpose of raising funds for the Hospital for Sick Children and Women realised the sum of £3085.

Drainage of the Monmouthshire Valleys.

In THE LANCET of Feb. 2nd, 1901, p. 362, reference was made to the provision of drainage for the western valleys of Monmouthshire. The report of the engineers appointed by the urban district councils of Ebbw Vale, Nantyglo, Abertillery, Abercarn, and Risca, and by the rural district council of St. Mellons has now been presented. The aggregate population of these six districts is 93,540, showing an increase of 20,589 during the last decade. There are still many portions of the valleys unopened, and as they are also comparatively near the sea-board and are well served with railways there is every likelihood of a considerable increase in the population in the future. The engineers were practically called upon to decide whether it would be more economical for the drainage of each district to be dealt with separately, either by irrigation or upon the bacterial system, or whether there should be constructed a joint sewer to serve the combined districts, discharging the sewage without treatment into the Bristol Channel. The initial cost of separate schemes is estimated at £254,000, to which sum would have to be added the expense of pumping, amounting if capitalised to £200,000. The cost of a combined sewer is estimated at £170,000, and although there would still be [illegible] keep this would [illegible] The only main [illegible] uthshire is that which was constructed between the years 1889 and 1892 for the Rhondda valleys and Pontypridd. This sewer, which cost £170,000, is 17½ miles long and discharges into the Bristol Channel about four miles above Cardiff, taking the sewage from a population of 145,000 persons. Leading into this main outfall are two subsidiary sewers along each of the Rhondda valleys, one of which is 10 miles and the other seven miles long, and which cost in construction about £60,000. The advocates of the privy-midden system so prevalent in the north of England are constantly declaring that, however suitable water-carriage may be for residential districts, it cannot be adapted to the houses of the working classes. This is quite contrary to the experience of those Welsh colliery districts, such as Rhondda and Pontypridd, where water-carriage is completely adopted and where the blocking of drains from improper usage is not by any means a common occurrence.

Abergavenny Cottage Hospital.

On June 28th the Marquis of Abergavenny formally laid the foundation-stone of the new cottage hospital and dispensary at Abergavenny. The building is to be erected on a site of land given by the corporation of the town.

Handel Cossham Memorial Hospital.

This new hospital, which is now being erected at Kingswood, will provide accommodation for about 50 patients. Mr. Cossham bequeathed nearly £100,000 for the structure, which sum will be available for the building and its endowment. The site comprises about four acres of land and is on one of the highest points in the neighbourhood, being nearly 370 feet above sea level.

July 1st.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Sanitary Inspectors' Association.

THE annual congress of this association was held in Glasgow on June 28th. A welcome to the delegates was offered by the Lord Provost who in the course of a short address reviewed some of the features of the recent epidemic outbreaks in the city. He paid a high compliment to the medical and sanitary departments for the energetic and efficient manner in which they had met the difficulties created by the invasion first of plague and later of small-pox. Drastic measures had no doubt been required to overcome the latter epidemic, but these had now proved successful and the city was nearly free from its presence. In connexion with these matters the Lord Provost announced his firm belief in vaccination and stated that his faith in it had been strengthened by what he had seen during the recent visitation. At the same time he urged the immense importance of sanitary precautions and sanitary conditions. Vaccination even if adopted universally in the city would be no excuse for failure to apply, or if necessary to increase, the compulsory powers of the health authorities. Recent experience had shown that it was in those areas of the city where the sanitary conditions were at their worst that small-pox obtained a position which it was very difficult to attack with success, and that on the contrary personal and domestic cleanliness, though not an absolute protection to the individual, meant the establishment of conditions antagonistic to the invasion and spread of the disease. Thus the general work of the sanitary inspector became a matter of first importance in relation both to the well-being of the individual citizen and to the protection of the whole community. His lordship was cordially thanked for the welcome which he had extended on behalf of the corporation and for the address which he had delivered to the delegates. In the course of the proceedings several references were made to the recent outbreak of small-pox in the city and the generally expressed opinion was that the management of this, considering all the difficulties of the position, had been decidedly successful. In the President's address figures were quoted to show that the death-rate of Scotland had decreased in each decade since 1861. The figures in the four decades terminating in 1870, 1880, 1890, 1900, were respectively 22·05, 21·63, 19·20, 18·74 average annual deaths per 1000, this being a reduction in the death-rate of 3·31 per 1000. Taking the eight large towns the death-rate had fallen from 28·2 per 1000 in the first decade to 20·9 per 1000 i the last, a reduction of 7·3. In connexion with the Compulsor Notification Act it was shown that about 50 per cent. of th notified cases of scarlet fever were treated in their own home and that this was an influence tending to the extension an persistence of the disease. The hospital treatment of eac case cost the community about £10. If compulsory remova to hospital were insisted on the number of cases would b rapidly diminished and very soon the expense to the community would be reduced. Another question which occupied the attention of the congress was the proposal to establish a port sanitary authority for the Clyde. Bailie King, in a paper on this subject, stated that they had every reason to believe that both bubonic plague and small-pox had passed into the city through the port. Though the corporation possessed the necessary powers under the Act of 1899 they had not yet constituted a port sanitary authority. This was due partly to the difficulty of securing the coöperation of other local authorities on the banks of the Clyde, but they expected shortly to overcome this and other difficulties. They had under consideration a scheme by which a complete defence would be set up for the purpose not only of preventing the entrance to the city by the river of persons suspected to be the subjects of infectious disease, but also of detaining dirty and insanitary ships until they were properly cleansed and disinfected. For some years they had employed a special inspector to devote his attention to seamen's and emigrants' boarding-houses with good results, and it only needed the establishment of a health authority for the port to render their sanitary armament complete. After some discussion a resolution embodying this view was passed unanimously and it was decided to send copies of this to the Secretary for Scotland and the Local Government Board Other subjects considered by the congress included the ventilation of houses, the standard for milk, &c.

Reconstruction of the Glasgow Royal Infirmary.

The unfortunate controversy regarding the rebuilding scheme is not apparently to be allowed to terminate. The Glasgow Institute of Architects is not satisfied with the explanation published on behalf of the executive committee and has sent to the press a further statement of objections In this it is contended that the plans as adopted are in many vital particulars inadequate and out of date and that the [illegible] lings, more particularly of the block [illegible], is bad. This block from its height, it is repeated, will shut out the sun and air from the rest of the buildings and will dominate and destroy the effect of the cathedral. The institute further criticises the manner in which the committee proceeded in the selection of the plan of reconstruction and urges that some of the rejected designs were free from the defects of the one adopted. Of course, all this must act prejudicially on the subscription lists, of which, indeed, little has been recently heard. And apart from other disadvantages delay has meant the appearance of appeals for funds from the University, the Technical College, and the Western Infirmary, all of which have schemes concerning which controversy is silent. In any case these must necessarily be serious competitors for public favour, but under the present circumstances it will not be surprising if the Royal Infirmary fails to obtain its due measure of practical support.

Hospital Saturday in Aberdeen.

June 29th was Hospital Saturday in Aberdeen. There was a monster procession of cyclists, members of friendly societies, the fire brigade, horses, machines, &c., through some of the principal streets to Duthie Park, where a military display and sports took place. There was a large attendance of the public. On the evening of June 28th there were also cavalry sports in the park, a detachment of the Scots Greys and the band of the Black Watch being present. The weather was fine on both occasions. The financial results are not yet known.

Sanitation at Fishers' Squares, Aberdeen.

The Aberdeen Town Council has called on the owners of properties at the Fishers' Squares, Footdee, in that city, to place all cellars or outhouses on an appropriate area, to introduce water and to fit up sinks in the dwelling-houses, and to provide for each a sufficient water-closet. In cases of default the town council will execute the works at the cost of the proprietors concerned.

July 2nd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Irish University Commission.

AT the annual meeting of the Royal University Graduates' Association held in Belfast on June 29th the following resolution was unanimously passed:—

> [illegible] Royal University Graduates' [illegible]he constitution of the Irish [illegible] grounds: first, that the Government have departed from the principle of appointing only such persons as are entirely unprejudiced on this important question and have included the names of several who have pronounced strongly biased views on one side; second, that the faculties are not represented thereon in proportion to their importance, and third, that there are on the commission certain members whose acts will form part of the subjects of inquiry and report.

At a meeting of the Higher Education Committee of the General Assembly of the Presbyterian Church in Ireland, held in Belfast on June 28th, resolutions were unanimously adopted opposing the establishment and endowment of any denominational university or college and protesting in the strongest manner against the exclusion of Trinity College, [illegible]n, as no settle- [illegible]ded as final or [illegible] University and [illegible]ointment of the [illegible] to the Government the earnest hope "that the constitution of the commission shall be such as to be a guarantee to the public that the great object aimed at shall be the advancement of education and not the promotion of any merely sectional or denominational interests." The Education Committee of the Presbyterian Church protest that as a large proportion of the members of the commission are known to be in favour of one policy (denominational education), while no recognised opponent of such a policy has found a place on the commission, any report the commission may make is discredited beforehand as likely to be partisan and one-sided.

Outbreak of Typhoid Fever in Belfast.

The medical officer of health reported to the Belfast City Council on July 1st at their monthly meeting that "there can be no doubt but that there is at present a serious outbreak of [illegible]." Between May 19th and June 15th, 1901, [illegible] of typhoid fever notified, as compared [illegible]ding month and 177 in the corresponding four weeks of last year. The outbreak first occurred in the Woodvale district which is a part situated in the higher portion of the city. It has since spread into the adjacent districts and at present is prevalent in all parts of the city. The only crumb of comfort is that whilst the number of cases has almost doubled, yet the deaths therefrom were 22 for the last four weeks, while in the preceding month they were 19; they were 29 in the corresponding month of last year. Dr. J. Fulton, dispensary medical officer of the district in which the outbreak occurred, attributed the majority of the cases to the dry weather in the month of May which had caused an accumulation of sewage in the sewers. A very animated discussion followed the presentation of the public health report in the City Council. The vice-chairman of the Public Health Committee (Dr. J. King Kerr) said that when on June 13th it was reported that 71 cases of typhoid fever had been notified during the week they had ordered their sanitary officer and medical superintendent, and with them Dr. Fulton and Dr. A. G. Robb, to supply them with a thorough and impartial report as to the cause of the outbreak and that their report was a very serious indictment of the state of affairs arising from matters connected with another public board in the city. It was, he said, a strong indictment of the Stoneyford catchment area, and they would present it when they had the fullest details. They had found no cause either in regard to sewers, houses, dams, or milk-supply for the outbreak of typhoid fever. Failing all these as causes they looked to the water-supply and they believed that the water-supply from Stoneyford catchment area was a menace to the health of the city. Councillor J. D. Williamson, M.D. R.U.I., took an entirely opposite view and said that it was not [illegible] trot out the [illegible] the sculleries [illegible] case occurred [illegible] had been ba[illegible] the "tippings" that were taking place all over the city, and on these places where the dirt was being cast houses would presently be erected without any regard whatever to the nature of the soil on which they were erected. He advised the water commissioners not to lay pipes through these impure soils as crackings of pipes might let impurities into the water. Alderman P. O'Connell, M.D. R.U.I., and Councillor A. V. Browne, L.R.C.P., L.R.C.S. Edin., also blamed the polluted subsoil. There can be no question that this continued friction between two public bodies like the corporation and the water commissioners of Belfast as to the cause of repeated outbreaks of typhoid fever in that city is a great mistake, and as a result nothing whatever is being accomplished to prevent the occurrence of the disease. The only solution is to get a skilled expert—a public health officer of experience from England—to come over and to investigate the whole question and to let the citizens know the truth and see on whose shoulders the blame for these annual epidemics rests.

July 1st.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Assistance Publique.

M. RANSON has just laid before the Municipal Council a report upon the work of the Assistance Publique in Paris. The report is a lively criticism of different abuses. First of all with regard to the nurses the report states that at the Lariboisière Hospital the principal nurses who are in charge begin their day at 5.30 A.M. and do not go off duty until 6 P.M., while five of their number keep on duty until 8 P.M., making a total day of 14½ hours which is broken only by 80 minutes which are allowed for three meals. About every seven weeks these nurses go on fatigue duty from 8 P.M. until 11 P.M.—that is to say, three hours' more work, making a total day's work of 17½ hours. If we consider that these unfortunate women must have half an hour to go to bed and as much time in the morning to dress and to perform certain indispensable toilet arrangements it can easily be seen that they have not more than five hours' sleep. It is very difficult for a young woman on whose shoulders are laid very delicate duties, for the right performance of which it is necessary that she must have all her wits about her, to avoid occasional failure in the presence of so much work. M. Ranson finally called the attention of the council to another point. He stated that three kilometres of string which had been ordered at a cost of 5 francs 85 centimes had taken six weeks to be delivered. An order form took 92 days to get from the Salpêtrière to the central depôt, although these two establishments are absolutely next door to one another. A patient who had been operated upon and for whom the surgeon had signed his ticket of dismissal had to stop in hospital for six weeks for the want of an orthopædic apparatus because the order for it had been pigeonholed all this time in the bureau of the Assistance Publique. This cost the administration four francs per day—that is to say, they had to pay 160 francs in addition to the cost of the apparatus. At the central depôt a machine for measuring cloth and costing 1500 francs had been waiting for two years for a governor, and during this time the attendants had handed out cloth in any quantity they liked. As a matter of fact, 30 per cent. of the bedding was in such a state that it would be far more preferable to destroy it than to keep it. The chief cause of this was the state of the disinfecting stoves, but the [illegible] and purifying mattresses also gav[illegible]ults. The mattresses were run thr[illegible] and were re-made in a hurry w[illegible] hair being thoroughly carded as they should be. For the workmen had to re-make the mattresses as fast as possible if they wished to make even two francs a day by them. Only 40 centimes were paid for mattresses. M. Ranson concluded by saying that the stock of linen which had almost run out would alone cost 3000 francs to renew. The Assistance Publique had hidden its deficits and had actually violated the law, because it gave out that a reserve of linen existed which did not exist. The institution would have to be re-constituted but money was wanting. The realisation of the promises of the new director is awaited to bring about a great reform.

Cerebro-spinal Fluid after the Injection of Cocaine.

At the meeting of the Society of Biology held on June 15th M. Ravaut and M. Aubourg communicated a paper in which they pointed out that after coming to the conclusion that headache after injection of cocaine into the spinal canal might be due to the presence of the cocaine in the cerebro-spinal fluid as well as to the increased tension they drew off some of the fluid some little time after the injection had been made. In this manner they managed to draw off some 20 cubic centimetres of cerebro-spinal fluid which spirted out with great force. As a rule the headache was very much diminished after this second tapping. With regard to the cerebro-spinal fluid drawn off it was generally found to be turbid. Chemical examination revealed the presence of cocaine, and microscopical examination showed that it contained a marked quantity of polynucleated cells which upon centrifugalisation made a clot upon the bottom of the tube. Sometimes the fluid clotted uniformly in the tube after it was left quite at rest. If the puncture was repeated during the following days it was found that at the end of three or four days the liquid, which had gradually become clearer, contained only lymphocytes and mononucleated cells and finally no formed elements of any kind. The fluid was found to be absolutely normal at a period varying from eight to 20 days after the first injection. Out of 21 patients only one was found to give perfectly clear cerebro-spinal fluid. It is obvious then from these observations that cocaine, however carefully sterilised, has a special influence upon the spinal membranes and brings about alterations in them which, although very fleeting in their effects, are in all points analogous to those observed in certain cases of meningitis although there is no trace of any microbe to be found in the cerebro-spinal fluid.

A Method of Detecting the Bacillus Typhosus.

M. Cambier explained at the meeting of the Academy of Sciences held on June 10th a method of detecting the bacillus typhosus. He placed a porous porcelain bougie in a large glass tube, both tube and bougie being half filled with bouillon sterilised at 110° C., and showed that when the bouillon contained within the bougie was inoculated with a pure typhoid culture, after some hours' subjection in a stove to a temperature of 37° C., that part of it in the glass immediately around the bougie, which had been originally quite limpid, presented manifest symptoms of the passage of the bacillus through the pores of the bougie. This property possessed by the bacillus typhosus of being able to traverse certain porous divisions suggested to M. Cambier the idea of making the following investigations in water. He infected a certain quantity of water within the bougie with the bacillus typhosus. The bougie was placed in a litre of bouillon at 38° C. As soon as a cloud appeared in the bouillon outside the bougie, with a delicate pipette he removed drops of the turbid fluid and inoculated with it different common substances—such as milk and potatoes, for example—which were afterwards submitted to microscopical examination and the agglutination reaction. Sometimes the passage of the bacillus typhosus was so complete that he found a pure culture of it within the bouillon. M. Cambier was able by this method to isolate the bacillus typhosus in the water of the Seine and of the Marne. His investigations are now being directed towards typhoid stools.

July 2nd.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Courts of Honour for the Army and Navy Medical Corps.

COURTS of honour are to be instituted for the medical officers of the army and navy. These gentlemen have hitherto not been under the jurisdiction of any court of honour, either military, naval, or civilian, the result being that in the event of a dispute arising between a medical officer of these services and another officer or a civilian medical man there was no means of deciding which party was in the right. The Imperial order which has been issued on this subject, after speaking in the highest terms of the merits of the army medical corps, says that His Majesty expects the courts of honour to maintain the general interests of all the members of the corps and to uphold the sentiments of duty and fidelity. The medical officers of the reserve, though under the jurisdiction of the courts, will not be entitled to act as judges. This course has been taken in their interest because they might otherwise be put to inconvenience in connexion with their practices. In cases where a charge has been brought against a medical officer of the reserve the matter must be adjudicated by the medical chamber previously to the verdict of the court of honour of the army medical corps. There will be two kinds of courts—one in each division for medical officers of the rank of staff surgeon and under and one in each army corps for the medical officers of higher rank. These courts are to be presided over by the chief medical officer of the division or of the army corps respectively, whilst the general commanding the division or the army corps is authorised to order the court to be convoked. The courts may either admonish the accused or may exclude him from the army medical corps in cases of grave ethical misdemeanour. The courts of honour for the navy medical corps will be composed in the same way, with the exception that in foreign ports where there might not be a sufficient number of medical officers to form a court the latter may in certain cases be composed of naval officers.

Rabies in Germany.

In Germany during the year 1900 there were 230 persons bitten by animals suffering, or suspected to be suffering, from rabies. This number showed a considerable decrease as compared with 1899 when 303 persons were bitten. Of the above 230 persons 187 were treated in the institution for infectious diseases in Berlin by injections of Pasteur's antirabic serum; the remainder were either treated at home by cauterisation or other methods or did not receive any medical treatment at all. It is remarkable that rabies did not develop in any instance either among the patients who received the injections or among the others, so that no case of rabies in the human subject occurred in Germany in 1900. The bites were inflicted by 162 dogs, five cats, and three cattle. Post-mortem examination showed the existence of rabies in 102 dogs, two cats, and three cattle, and of suspected rabies in 44 dogs and one cat.

The late Professor Langenbuch.

Professor Carl Langenbuch, chief surgeon to the I Hospital, died in Berlin on June 9th. He was born at K in 1846, became qualified in Berlin in 1869, and took part a military surgeon in the war of 1870–71. After having acted as an assistant to the late Professor Wilms he was appointed chief surgeon to the Lazarus Hospital, an office which he held till his death. His principal work was on the surgery of the liver, and as early as 1882 he performed total extirpation of the gall-bladder, and in 1888 made a partial resection of the liver. He described his views in a monograph entitled, "The Surgery of the Liver and Gall-bladder" which formed a part of the "German Surgery" edited Professor Bruns. He was also the author of some essays military surgery, a subject with which he was very acquainted, as he had taken part not only in the F German, but also in the Turco-Russian war. Profes Langenbuch was very much liked by the profession Berlin and his early death is in every way greatly regretted.

July 1st.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

The Plague.

THE plague this year has taken a new departure, but the present generation has become so accustomed to hearing of cases of plague in different parts of the world that there is very little public interest in its apparition. In fact, the sceptics sway public opinion in the newspapers and in so by declaring, on the one hand, that it is not plague and that the sanitary officials are quite wrong about it all, and on the other hand, they state that the plague is of no conseq because it has evidently been lying dormant in the coun since 1844 and the medical men have never discovered it until now. Anything which prevents a panic is good, so that the ignorant had better be left to their own beliefs while the intelligent can obtain daily information from the bulletins issued by Mr. Pinching, the Director-General of the Sanitary Department in Cairo. In 1899 plague spoiled the spring months of Alexandria by appearing there, but it had the courtesy not to travel away from the sea coast. The following year, in the months from May to August, it was found at Port Said, but again it showed no disposition to attack the rest of the country. On neither occasion could its first onset be traced, but it is fairly obvious that it must have come from a neighbouring country. Now for the third time it has been discovered not in Alexandria r Port Said, which seem to be free, partly because they are both unnaturally clean and whitewashed, but in three inland towns, Zagazig and Mansourah, both in the Delta, and Minieh in Upper Egypt, several miles above Cairo. The simultaneous discovery of the disease in three scattered places shows that the microbe must have been conveyed by some moveable agent, such as clothes, carpets, or furniture. One cannot quite picture a rat wending its way or being carried by train with the family goods of an ex-plague patient, but it does not require much imagination to think of the rat-fleas being conveyed in clothes or rugs, from a dirty hovel on the sea coast to an insanitary mud cabin in the interior of the country. Anyone who knows the poorer Egyptians is aware that the last thing they would think of would be to beat, to shake, or to wash the prayer carpets and matting which they carry about with them. It is noteworthy that all the places attacked were picked out by cholera as suitable homes in the epidemics of 1883 and 1896 Now that plague has arrived in our midst we have not time to stop and to think why it never came before, but the principal object of life is to work at the various spots infected to prevent anything like a place infection, for we all know what happens to a city like Bombay where all precautions were neglected for the first few months. The plague can be fought in any country so long as there are plenty of energetic workers, some money, a docile population, and a government determined to fight. At present there are enough English workers, though there is no doubt that a permanent staff of anti-plague officials should be added for the next few years to the sanitary department. There are 10,000,000 Egyptians in Egypt, but they are of no use to fight plague unless they are controlled by a handful of Englishmen, in which case they do extremely well. The average European cannot compete *with the Anglo-Saxon, whose energy, fighting-powers, tenacity*, and conscientiousness about details, are all called into play by the fascination of fighting an unseen foe whose ravages are fairly conspicuous. There is no doubt that the Englishman likes policing the world and to be turned loose into an insanitary town, and to be told to compel the inhabitants and [illegible] clean exactly suits the Anglo- [illegible] r, the natives obey his orders [illegible] more than they will do for any [illegible] eans. Major Garner and Dr. [illegible] disease in and around Zagazig and Dr. Goodman is at Minieh, while Dr. Graham superintends the work at Mansourah and other places. The various doctors in the medical school and other departments of the Egyptian Government have been told to hold themselves in readiness for employment in the provinces. There are two satisfactory things to be recorded. The various sanitary returns show that the country is in a healthier condition than usual and also that the old plague season used always to finish in an epidemic form at the end of June. In other words the plague microbe does not like excessive heat and will not now have time to take root and to destroy before the summer heat is upon us.

Cairo, June 11th.

Medical News.

THE International Association for the Advance*ment of Science, Arts, and Education* will hold its second international meeting at Glasgow, in the University and in the [illegible] Exhibition, from July 29th to Sept 27th. [illegible] as a link among universities and learned [illegible] ie of the most important functions of the [illegible], as at Paris last year, to study and to [illegible] of scientific, geographical, and other [illegible] the exhibition by means of lectures and [illegible] monstrations and visits under skilled guidance. The various national groups which coöperated last year at Paris will again be represented at Glasgow, and their lectures and conferences, &c., will include pure and applied physics and chemistry, electricity and engineering, agriculture and forestry, geography and colonisation, hygiene, Scottish history and archæology, and fine art. Much attention is also being paid to education in its many branches—*child study*, nature study, methods of science study, modern language study, manual and technical education, museums, geographical education, history and organisation of secondary education, the whole concluding with a series of conferences on "Immediately Realisable Progress in Education." The general secretary is M. Liard, Permanent Secretary of State for Higher Education, Paris, assisted by Professor Patrick Geddes.

THE BRISTOL QUEEN VICTORIA MEMORIAL FUND.—Up to the present the sum of £4665 has been received towards this fund. It is hoped that £5000 will be raised towards the national memorial and £10,000 for the further endowment of the convalescent home on Durdham Down, the opening of which was one of the last public acts of the late Queen.

THE WEATHER IN NEW YORK.—It is stated that 225 deaths and 327 cases of prostration were caused by the heat in greater New York during the 24 hours ending at 2 A.M. on July 3rd. 196 deaths are reported from other cities. During the 24 hours ending at 2 A.M. on July 2nd 87 deaths occurred in greater New York from the same cause and there were 183 cases of prostration.

PRESENTATIONS TO MEDICAL PRACTITIONERS.—At the town hall, Lochmaben, Dumfriesshire, on June 8th, Mr. Thomas Reid, M.D. Glasg., who has been for 25 years in practice in Lochmaben, was presented with a gold lever watch, a gold albert chain, and a richly-chased silver bowl on ebonised plinth. Ex-Provost Halliday presided over the company, which numbered about 150, and the presentation was made by Captain Carthew-Yorstoun, convener of the county. The inscription on the watch was as follows: "Presented to Thomas Reid, Esq., M.D., by his friends on the completion of 25 years' practice in Lochmaben, as a token of appreciation and esteem. 18th May, 1901." The silver bowl, which was the gift of the ladies, bore a similar inscription.—Mr. William Atkin Thompson, M.R.C.S. Eng., L.R.C.P. Lond., resigned the post of resident medical officer to the Weston-super-Mare Hospital and Dispensary on June 10th, and before leaving the hospital he was presented with a Swan fountain pen with engraved gold bands and an aseptic, silver-plated, all-metal hypodermic syringe in case, together with a testimonial, signed by a large number of the dispensary patients, "as a mark of their esteem and good wishes for his future career and in return for his kind attention to them"—The members of the Men's Ambulance Class of the Halifax Centre of the St. John Ambulance Association have presented their lecturer, Mr. J. Crossley Wright, M.A., M.B Cantab., with a medicine-case suitable for attachment to bicycle or motor-car. The case contained 13 phials of "tabloid" brand medicines, and sundry emergency dressings and instruments.—On June 22nd the members of the Sharpness branch of the St. John Ambulance Association presented *Mr. Walter Robert Awdry, M.B. Durh.*, M R C.S Eng., with a tennis racquet with silver shield containing a suitable inscription as a mark of appreciation for his services as honorary lecturer to the class.

THE ARMY MEDICAL SERVICE INQUIRY.—As we go to press we learn that Mr. Brodrick has announced in the House of Commons that the committee which has been recently appointed will not examine witnesses and will sit in private.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ELECTION OF MEMBERS OF COUNCIL.

THE thirteenth election of Fellows to fill the vacancies in the Council of the College under the new regulations was held in the Library of the Royal College of Surgeons of England, Lincoln's Inn Fields, on Thursday, July 4th, between 2 and 4 P.M. The result of the voting was:—

	Votes.	Plumpers.
MR A. W. MAYO ROBSON ..	332	4
MR. W. WATSON CHEYNE ...	302	2
MR. CLEMENT LUCAS	259	60
MR. C. MANSELL MOULLIN ...	235	67
MR. J. H. MORGAN	226	32
MR. J. BLAND-SUTTON	193	25
MR. H. H. CLUTTON	145	16
MR. JORDAN LLOYD	93	4

Mr. Mayo Robson and Mr Watson Cheyne are therefore re-elected and Mr *Clement* Lucas is elected.

768 Fellows voted, 18 personally and 750 by post; 5 proxies were received too late.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The New Factory and Workshop Legislation.

THE Bill of the Government to amend the Factory and Workshop Acts has not, so far, been very much altered by the Grand Committee on Trade. In the first clause, which deals with the power of the Home Secretary to make regulations for the safety of persons employed in dangerous trades, words have been inserted which extend slightly the possible operation of these regulations. A good deal of time was spent over the clauses dealing with outwork and outworkers. As the Bill stands, the employer is required to prepare a list of outworkers and to furnish copies of it to the Home Office inspector for the district and to the district council, and Mr. Ritchie has promised to bring up at a later stage of the Bill a clause providing that where a district council neglects its duties in connexion with outwork and outworkers the Home Office inspector may step in and see to them. In the clause prohibiting outwork in places where there is infectious disease words were inserted to confine the operation of the clause to the infectious diseases "required to be notified under the law for the time being in force in relation to the notification of infectious diseases." On the clause prohibiting outwork in places injurious to health there was a long debate as to whether the administration of the clause should rest with the district council or the Home Office inspector, and Mr. Ritchie offered by way of compromise a provision to the effect that when default on the part of the district council was suspected there should be power to send a Home Office inspector to inquire. The prevailing sense of the Committee seemed to be that the local authorities would not fail in their duty in this connexion and that they might be trusted.

Isolation Hospitals Bill.

This Bill has now passed both Houses of Parliament and awaits the Royal assent. The measure is designed to encourage the establishment of isolation hospitals and to improve their character. It gives power to local authorities under the Public Health Act of 1875 who have provided isolation hospitals to transfer them to the county council and it enables the county council to make an annual contribution towards the maintenance or extension of isolation hospitals remaining in the hands of local authorities under the Public Health Act of 1875. It also provides for borrowing money and for county councils being represented on hospital committees.

HOUSE OF COMMONS.

THURSDAY, JUNE 27TH.

Roentgen Rays in the War.

SIR BENJAMIN STONE asked the Secretary of State for War whether the Army Medical Department had made any report as to the application and value of the use of Roentgen rays in the military hospitals in South Africa during the war; whether expert instruction had been given in the several hospitals in applying x rays; and whether illustrated records had been obtained for future guidance.—Mr. BRODRICK replied: No report has been made on the use of Roentgen rays in the war nor will it be made until the war is over. Instruction is given in certain hospitals at home in the method of applying the x rays, but could not be readily given in South Africa. Illustrated records have been obtained and a large number have been forwarded to the Army Medical School.

Medical Officers of Health in Scotland.

The LORD ADVOCATE, in reply to question by Mr. WEIR, said that he was informed by the Local Government Board in Scotland that since May 15th, 1894, 72 burgh local authorities had appointed medical officers of health. Except in the case of two of these burghs all the medical officers of health appointed held a public health diploma.

The Reorganisation of the Army Medical Service.

Mr. BURDETT-COUTTS asked the Secretary of State for War if he could now state what progress he had made with his scheme of reform of the Army Medical Service; when he proposed to bring it forward and what opportunity would be afforded the House of discussing it; and if he could give any information as to the composition of the committee which he proposed to appoint to advise in the matter.—Mr. BRODRICK said: In reply to this and similar questions I beg to say that I have received a number of suggestions and representations from various quarters and that a committee of experts to consider a scheme which I have drawn up for the future organisation of the army medical service will be shortly appointed. The committee will consist of the following members: Mr. Howard H. Tooth, C.M.G., M.D. Cantab., F.R.C.P. Lond., St. Bartholomew's Hospital; Mr. George H. Makins, C.B., F.R.C S. Eng., St. Thomas's Hospital; Mr. Alfred D. Fripp, C.B., F.R.C.S. Eng., Guy's Hospital; Sir F. Treves, K.C.V.O., C.B., F.R.C S. Eng., London Hospital; Mr. Alexander Ogston, M.D. Aberd., Scotland; Lieutenant-Colonel A. H. Keogh, R.A.M.C., C.B., M.D. R.U.I., Ireland; Mr. E. C. Perry, M D. Cantab., F.R.C.P. Lond., Senate of London University; Surgeon-General W. R. Hooper. I.M.S., C.S.I., President of the Medical Board, India Office; and two officers who will be named by the Commander-in-Chief to represent the army. The secretary will be Major H. E. R. James, R.A.M.C., F.R.C.S. Eng., and I propose to take the chair of the committee myself.

Dr. FARQUHARSON asked whether the committee would close its sittings before the end of the present session?—Mr. BRODRICK replied: I do not know. It is much more important that they should come to a correct conclusion than that we should hurry them in the performance of the task assigned to them.

Dr. FARQUHARSON asked whether the right hon. gentleman was aware of the great difficulty of getting candidates for the Royal Army Medical Corps, a difficulty which would amount to impossibility before long if the intentions of the Government were not made known.—Mr. BRODRICK replied: The difficulty may become accentuated, but I would rather make a temporary arrangement and put the corps permanently on a good footing than be in a hurry to arrive at a conclusion.

Dr. THOMPSON asked the right hon. gentleman whether he would not add to the committee a representative of the medical profession in Ireland.—Mr. BRODRICK: No, sir; I think it would be very undesirable to make the committee too large and I am sure that all questions connected with Ireland will be most carefully considered, there being already one representative of Ireland on the committee.

In reply to another question by Dr. THOMPSON Mr. BRODRICK said: The object of the committee is to consider a scheme for making it possible to get proper medical officers in the future and a properly organised corps, and there is no idea of taking evidence as to the grievances of members of the Royal Army Medical Corps themselves.

FRIDAY, JUNE 28TH.

The Case of Dr. Long.

When the House was in Committee of Supply on the vote for the salary of the Chief Secretary for Ireland Colonel SAUNDERSON raised the case of Dr. Long, about which there had been several questions asked. Colonel Saunderson explained that Dr. Long was a skilled medical practitioner who in 1893 went to Limerick as the agent of the Irish Church Missions, an organisation one of whose objects was the conversion of Roman Catholics to the Protestant faith. In his work as a proselytiser Dr. Long was pursuing a perfectly legal object. A large number of the poorest class of the people of Limerick attended at Dr. Long's house and received medical ministrations from him gratis, and while they were there he spoke to them on the subject of religion; but he made no bargain with them—whether they liked his religious opinions or not they got his services as a medical man. [illegible] to them certain of the priests unde[illegible]g. One of them went to his surger[illegible] he place and told them never to return. After that Dr. Long was publicly assaulted in the streets and assailed with stones, eggs, and cabbages, which was the natural result in Ireland where a man was held up to execration by the priests. He claimed from the Chief Secretary for Ireland that more police protection should be given to Dr. Long.—Mr. WYNDHAM, replying to this and other speeches on the subject, said that Dr. Long would be protected by the law in the course he was pursuing, but he could not help saying that he considered that course a most unfortunate one; it was a course which might be followed with considerable advantage in China or Peru, and even in this country, but it could not be pursued with any great public benefit in Ireland. Dr. Long went to the Roman Catholic town of Limerick as the emissary of a missionary society and opened a dispensary there. It was very wrong, of course, that that action should have led to disturbances. It was the duty of the police to protect Dr. Long and he would be protected. But he ventured to say that disturbances would occur under similar circumstances in any part of the world, and certainly in Belfast, if any of the regular orders of the priesthood were to open a mission on the same lines to the Protestants. The duty of the Government was to protect such persons, acting as they did legally, from molestation, and that duty would be performed, but he should express his opinion that such a state of affairs was most regrettable and his hope that all persons would use their best endeavours to allay any irritation that might have been aroused.

MONDAY, JULY 1ST.

A Standard for Butter.

Mr. HANBURY, President of the Board of Agriculture, announced that the committee on this subject will consist of Mr. Horace Plunkett, chairman; Professor Thorpe, principal chemist of the Government laboratories; Sir Charles Cameron, medical officer of health and public analyst of Dublin; Professor Thompson, president of the Institute of Chemistry; Major Craigie, of the Board of Agriculture; Mr. George Gibbons, a well-known agriculturist in the West of England; Mr. Kearley, M.P.; Mr. Christopher Dunne, chairman of the Cork Butter Market Trustees; and Mr. Anderson, secretary of the Irish Agricultural Society. Mr. Hanbury added that he also hoped to obtain the services of Mr. John Gilchrist, a well-known butter-maker.

TUESDAY, JULY 2ND.

Contamination of Drinking-places for Animals

Mr. LOUIS SINCLAIR introduced a Bill to prevent the contamination of public drinking-places for animals.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning at each week, for publication in the next number.*

BONNEY, W. F. VICTOR, M.D., M.S. Lond., F.R.C.S. Eng., M.R.C.P Lond., has been appointed Registrar to the Chelsea Hospital for Women.

BREW, RICHARD HUGH, L.R.C.P. Edin., has been appointed Medical Officer of Health of the Clutton Rural District, vice G. H. Whicher, resigned.

CAMPBELL, ALFRED, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Vaccinator at Young, New South Wales.

EVERED, ARTHUR C., L.R.C.P., L.R.C.S. Edin., L.F.P. & S. Glasg., has been appointed Special Medical Officer for Plague at Albany, Western Australia.

FETHERSTONHAUGH, CHARLES, M.B., Ch.M. Dub., L.R.C.S. Irel., has been appointed Vaccinator at Corryong, Victoria.

FITZGERALD, JAMES, M.B., Ch.M. Edin., has been appointed Vaccinator at Kalangala, New Zealand.

GODFREY, PATRICK J., L.R.C.P., L.R.C.S. Edin., has been appointed Health Officer at Port Strahan; also Medical Off[illegible] Port Macquarie, Tasmania.

GILES.—On June 22nd, at St. Nicholas parade, Scarborough, the wife of Leonard Giles, M.B., F.R.C.S., of a son.

HILLS.—On June 25th, at New Bridge House, Upwell, the wife of W. C. D. Hills, M.R.C.S. Eng., L.R.C.P. Lond., of a daughter.

MARRIAGES.

[illegible] the [illegible] ssy, [illegible], to [illegible] by the Rev. C. [illegible] LL.B., D.Sc., in [illegible] Mysore, son of [illegible] London, to [illegible] daughter of the [illegible] Granger of 2, Grosvenor terrace, Glasgow.

WATSON—RANKIN.—On June 27th, at St. Andrew's, Rochford, by the Rev. H. A. Watson, George Trustram Watson, M.A., M.B., B.C. Cantab., F.R.C.S. Eng., to Dorothy Nora, daughter of Hugh Rankin.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

FEES AT CORONERS' INQUESTS.

To the Editors of The Lancet.

Sirs,—Can you tell me to what fee a medical witness is entitled for giving evidence at a coroner's inquest (1) if he has made a post-mortem examination of the body, and (2) if no such examination has been made. In London one usually receives two guineas in the first case and one guinea in the second. The coroner here orders one guinea in the first case and nothing in the second, and he refers me to Section 22 of the Coroners Act, 1887. I should be glad if you would enlighten me as to whether the London or local coroner is in the right.

I am, Sirs, yours faithfully,

July 2nd, 1901. G. H. F.

*** There is no question about the fees as regards inquests on persons not dying in a public institution. If a practitioner gives evidence by a coroner's orders without making a post-mortem examination he is entitled to a fee of one guinea. If he gives evidence and in addition makes a post-mortem examination *as ordered by the coroner* he gets a fee of two guineas. But by Section 22, subsections 1 and 2, of the Coroners Act of 1887 a medical witness (1) gets no fee for making a post-mortem examination which is not ordered by the coroner, and (2) when an inquest is held on the body of any person who has died in a public institution, even if supported by endowment or voluntary subscriptions, the medical officer of such institution shall not be entitled to such fee or remuneration. If our correspondent refers to inquests on the bodies of persons dying in the hospital the coroner, even if he have ordered a post-mortem examination, is within the Act in allowing no fee at all; but apparently the coroner whom our correspondent mentions allows one guinea for the post-mortem examination on a person dying in the hospital.—Ed. L.

WHAT IS CARBONATE OF SODA?

It is a pity that some understanding cannot be arrived at as to what is really indicated by the popular names of many drugs in common use. Until such an understanding is laid down it seems to us that in many instances proceedings taken under the Food and Drugs Act will prove silly, abortive, and vexatious. Last week, for example, a druggist was charged with selling bicarbonate of soda when carbonate of soda was asked for. The indictment was that this substitution was to the prejudice of the purchaser. It was a stupid ground for a prosecution, although strictly speaking the article asked for was as a matter of fact not supplied. But pure anhydrous carbonate of soda is seldom, if ever, supplied to the public and the public never expect it, although they invariably ask for carbonate of soda. Indeed, true carbonate of soda is an alkali possessing corrosive action and might prove harmful, while it could never serve the great number of purposes to which the bicarbonate is very commonly applied. Of course, the bicarbonate of soda is one of the carbonates of soda, for there are several. It just happens to be that bicarbonate of soda is in very common request, but the public do not know the difference between it and the carbonate. Did they know and understand the difference this prosecution might have been reasonable, as it certainly would have been if sulphate of soda had been asked for and the bisulphate had been supplied.

INCOME-TAX OVERCHARGES.

To the Editors of The Lancet.

Sirs,—The Chancellor of the Exchequer, in his recent speech at the Mansion House, stated that the cost of the wars in which this country has been engaged in South Africa, China, and in East and West Africa, has, notwithstanding the fact of the heavy increase in the income-tax, and the tax on coal and sugar, rendered it necessary to raise a loan of £127,000,000 within the last two years. When it is remembered that the war expenditure is still going on with no immediate prospect of ceasing in the near future the income-tax payer cannot expect early relief in the rate now in force, and, though the Chancellor of the Exchequer was, doubtless, very much in earnest when he said he would resist the temptation, if possible, to ask for another 2*d.* next year, it is to be feared that the rate will not then be less than 1*s.* 4*d.* It is, therefore, the more necessary to bear in mind that it is possible in very many cases to obtain relief from excessive assessments, and also by way of abatements that have not already been allowed. In the matter of overcharges under Schedule D, those who paid too much for the year 1900–1901 should at once appeal against the assessment for that year, or they may be told that they are too late. Thousands of people who pay taxes for which they are not liable can now claim repayment for three years; the amount recoverable might in the case of many amount to upwards of £45. We shall be pleased to advise your readers gratuitously whether they are entitled to any repayment in respect of tax deducted from rents, interests, dividend, annuities, &c., whether paid "free of income-tax" or not, and also in respect of life assurance premiums, on their sending us full particulars of their incomes from all sources and a stamped directed envelope for reply.

We are, Sirs, yours faithfully,

The Income-tax Adjustment Agency, Limited.

Poultry, London, E.C., July 3rd, 1901.

A POINT IN ETIQUETTE.

To the Editors of The Lancet.

Sirs,—Kindly give me your advice through The Lancet on the following point of etiquette. I was engaged for a confinement some few week ago. The confinement came off recently and being engaged at another case I could not go; messenger said I should be wanted in about three-quarters of an hour, and left on the understanding that I would get down as soon as possible. On my subsequent arrival about a quarter of an hour after appointed time I found they had called in another medical man and delivery had just been completed—case said to be urgent and forceps delivery. I saw the patient and expressed my sorrow at not being able to attend and left the room and awaited the other medical man downstairs in order to see about the subsequent attendance; and this is the point on which I require your advice. When I have been called in on an emergency I have always turned the case over to the medical man who had been engaged—the patient being his—and come to some agreement or other as to fee with him. In this case, however, he told me that he did not know I had been engaged until I entered the bedroom, and said he had been asking the patient whether he should continue or not. I certainly think this is wrong, as it practically leaves me without a voice in the matter, and had I thought that he was going to act in such a manner I should have asked the patient myself, as of course I have the prior right. As it is I simply left the house and decline to have anything further to do with it. Of course, in good-class patients such a thing would not have happened, but in the above—a decent working-man class—the suggestions advanced by the accoucheur are often acted upon and the former medical man loses the family as well eventually.

I am, Sirs yours faithfully,

July 2nd, 1901. Lex.

*** The time-honoured rule is that when a practitioner is called to an urgent case he should, when the emergency is provided for, resign the case to the medical adviser in ordinary. It is very usual for the gentleman called in at the beginning to continue in attendance until the end by arrangement with the patient and the family practitioners, but it is not correct that the suggestion of so continuing should come from him.—Ed. L.

MEDICAL TESTIMONIALS.

A correspondent has forwarded us a circular most of which we reproduce below. We have suppressed all names and addresses.

"To Medical Men and Others.

"We have the permission of Dr. —— to publish the following letter:—

"The —— Cycle Co., Ltd., "——, ——, 26th April, 1901.

"Dear Sirs,—I have recently been riding one of your —— cycles with free wheel and band brake and you may be interested to hear that I consider it the best bicycle I have ever ridden. I began cycling on "bone-shakers," then used a "phantom," and then the "ordinary," and have since ridden safeties of all makes and patterns, having at present three "——" in the house. I am thus a fair judge of a machine and I wish to say that I consider —— —— gear to possess all the advantages claimed for it. Its most conspicuous feature is the absence of strain on the frame when the rider uses force, as in climbing hills and travelling against the wind. The ease with which the machine moves under these circumstances was a revelation to me. You also use a good free wheel, which is really free, and your two point band brake is without doubt the best in th market.

"I have never before written anything of the nature of a test monial, and I now write you simply to express the admiration whic your cycles demand. In my professional work I am constantl asked by ladies if they may cycle, and I often have to say to m more delicate patients that they must not go too fast nor too fa and must avoid riding up hills and against strong winds. I sha now be able to tell them that by riding a —— with free wheel an band brake they will be able to keep pace with much stronger ride without fear of fatigue or over strain.

"I am, Sirs, yours faithfully,

"—— ——, M.A., B.Sc., M.D."

In our issue of June 29th, p. 1876, we published a letter from Dr. P. Mannix and Dr. B. W. Hogarth in which they expressed the opinion that "if a man supplies us with good bicycles or motor-car we see no objection to testifying to it, even though we do belong t the medical profession." Neither do we see any objection provide that the testimonial is given as from an ordinary citizen. But w consider that for a medical man's name, qualifications, and appoint ments, together with his full address, to be distributed broadcast t all and sundry is not becoming—even though the bicycle in question is a good one.

ASBESTOS SLATE.

We have received from the manager of the Calmon Asbestos and Rubber Works, 3, Haydon-street, Minories, samples of asbestos slate identical with the material supplied for the construction of the asbestos house used by Field-Marshal Count Waldersee in China. The specimens are not only fireproof but waterproof also and the material affords some protection against the ingress of dust and insect pests. It is very strong and durable and cleanly. The asbestos house has been adopted by military authorities because, for one thing, it is easily moveable; moreover, asbestos rotection against climatic influences, being an efficient insulator gainst both heat and cold. The asbestos slates are made in metre quares either one-eighth of an inch or a quarter of an inch thick, ccording to requirements.

THE TREATMENT OF ACNE.

To the Editors of THE LANCET.

SIRS,—I should be pleased to have the experience of any of your many readers who have treated with success cases of acne vulgaris. I am a medical man of many years' standing, aged 47 years, and suffer very severely from attacks of acne; it is covering my face with scars from the oft-repeated attacks, and I have tried all the ordinary remedies, including taking a long holiday and rest, and still they appear in crops on the face, especially the forehead. Any help to a fruitful result will be gladly welcomed.

I am, Sirs, your faithfully,

June 27th, 1901. ACNE.

HOMES FOR INEBRIATES.

To the Editors of THE LANCET.

SIRS,—Can anyone give me the names or addresses of homes for inebriates where after a voluntary entry by the patient he can be detained for a definite period agreed to by the patient and to which, if he leaves, he can be brought back?

I am, Sirs, yours faithfully,

July 3rd, 1901. PHENAD.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports, should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether [illegible] *tion, must be* [illegible] *their writers,* [illegible]

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1901, which was completed with the issue of June 29th, and the Title-page to the Volume, are given in this number of THE LANCET.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1901 will be ready shortly. Bound in cloth, gilt lettered, price 18*s*., carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

During the week marked copies of the following newspapers have been received:—*Bristol Mercury, Liverpool Daily Post, Yorkshire Post, Leeds Mercury, Woolwich Herald, Reading Mercury, Windsor and Eton Express, Mining Journal, South African News, Dover Express, Hertfordshire Mercury, Yarmouth Advertiser, Surrey Advertiser, Weekly Free Press (Aberdeen), &c.*

Communications, Letters, &c., have been received from—

A.—Dr. J. M. Atkinson, Puddington; Dr. J. C. Abbott, Birmingham; Association for Oral Instruction of Deaf and Dumb, Secretary of.

B.—Dr. L. C. Bruce, Murthly; Bromsgrove, Medical Officer of Health of; Mr. P. Benham, Lond.; Dr. C. Basan, Lond.; Mr. C. Birchall, Liverpool; Messrs. Bedford and Co., Lond.; T. B. Browne, Ltd., Lond.; Bristol Royal Infirmary, Secretary of; Birmingham University, Dean of Faculty of Medicine of; Mr. J. B. Bate, Isleworth; Mr. S. W. Belderson, Lond.; Messrs. C. Barker and Sons, Lond.; Dr. J. J. Buchan, Hamilton; Mr. E. Stanmore Bishop, Manchester; Mr. A. Burr, East Grinstead.

C.—Dr. R. H. Crowley, Bradford; Messrs. Cassell and Co., Lond.; Messrs. Cosenza and Co., Lond.; Mr. G. L. Cheatle, Lond.; Cumberland and Westmoreland Asylum, Carlisle, Clerk of; Mr. D. L. Clay, Wellington, New Zealand; Clayton Hospital, Wakefield, Hon. Secretary of; Croydon Borough, Medical Officer of Health of; Chester General Infirmary, Secretary of; Messrs. T. Christy and Co., Lond.; Calmon Asbestos Works, Lond.; Mr. J. S. Cunningham, Penzance; City Asylum, Gosforth, Newcastle-on-Tyne, Secretary of; C. R. M.; Mr. Mayo Collier, Lond.

An original and novel feature of "The Lancet General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in The Lancet.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. Charles Good, The Lancet Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

The Lancet can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

An Address

ON

TUMOURS OF THE BLADDER AND ENLARGED PROSTATE.

Delivered before the Hull Medical Society

BY DAVID WALLACE, C.M.G., F.R.C.S. EDIN.,
ASSISTANT SURGEON TO THE ROYAL INFIRMARY, EDINBURGH.

[AFTER some introductory remarks Mr. Wallace said:]

With the introduction of the light internal cystoscope in 1887 the surgery of the bladder became much wider in its scope and more accurate. Diagnosis and prognosis both made enormous strides because definite opinions could be arrived at much earlier in the course of an illness. Dicta which for long had been thoroughly believed were found to be inaccurate and often misleading. Especially this was so in the case of hæmaturia. A patient with hæmaturia might have no other symptom to indicate whether the blood was renal or vesical in origin and not infrequently a wrong diagnosis was made or delay in proper surgical treatment was so great that the likelihood of successful treatment was much lessened. In tumours of the bladder this was particularly the case. Frequently in such tumours a causeless, symptomless bleeding is the first indication of anything being wrong, but diagnosis was often impossible unless a cystotomy, as introduced by Sir Henry Thompson, was performed, and surgeons hesitated to do this without more evidence of the probable seat and cause of the bleeding. Further evidence is got by cystoscopy. To-day in such a case the bladder would be examined cystoscopically and either negative or positive evidence of a tumour would be found, and being got at an early period treatment would be much more satisfactory than it had been formerly. Let me illustrate this by quoting two cases.

CASE 1.—A man, aged 60 years, had a long-standing history of intermittent hæmaturia. For three years he was treated on the assumption that the blood emanated from the kidney or kidneys. He was seen and was treated by several physicians without benefit. The bleeding was occasionally very profuse, but as a rule it was moderate in quantity and was intimately mixed with the urine. There was no other symptom and careful examination of the urine made on many occasions failed to give any clue to the origin of the blood. On cystoscopic examination a large tumour attached to the right lateral wall of the bladder was seen. Suprapubic cystotomy was performed and the greater part of the tumour was removed. He made an excellent recovery. Bleeding recurred at the end of a year, but the patient lived for four years after the operation. The bleeding was at no time so profuse as it had been before operation and the patient was able to perform his business to within a few months of his death.

CASE 2.—In the case of this patient, who was 35 years of age, the first hæmorrhage had occurred one year before I saw him. It was causeless and was associated with no other symptom. There was nothing seen on careful examination of the urine. He c[illegible]ge, otherwise he [illegible]pic examination a t[illegible] on the right lateral wall. It was of about the size of a walnut. I removed the growth through a suprapubic opening and 13 months after the operation the patient was perfectly well. There was no bleeding or other symptom of recurrence.

These two cases illustrate the difference between early and late diagnosis, and probably the after-history will show the value of early treatment in the second case.

The proof of the importance of the cystoscope is partly demonstrated so far as tumours are concerned by the number of tumours of the bladder which are now treated. Previously to 1888 they were considered rare—now they are known to be of comparative frequency. I have during the last ten years seen upwards of 50 cases. Two books—Albarran's and Clado's—have been written on the subject, and Hurry Fenwick, Barling, Nitze, Guyon, and others have reported series of cases from time to time. This frequency is not, I believe, because vesical tumours are more frequent in their occurrence now than formerly, but it is because they are more often diagnosed. We are all familiar with this in other diseases. Mr. R. J. Godlee in a paper on Actinomycosis[1] refers to this point about new diseases, or increased frequency of occurrence. It is not that they are more common, but when once a disease has been pointed out we are more on the alert to discover it when a case comes before us.

Regarding the varieties of bladder tumour I may first exclude those of extension from adjacent parts, and also those which have originated in the prostate. The classification which I give and my remarks on symptoms and treatment refer to primary tumours of the bladder wall. Albarran's classification is, I think, the best: (1) epithelial tumours: *simple* papilloma and *malign* epithelioma; (2) connective tissue tumours: *simple* fibroma, *malign* sarcoma, myxoma, and fibro-myxoma; (3) tumours of special tissues: angiomata and myomata; and (4) cysts: dermoids and hydatids.

Regarding pathologically simple or malign growths it is right to say that the former may clinically prove fatal just as the latter do unless suitable treatment is carried out. They give rise to hæmorrhage, cystitis, and secondary renal affections and it is from these that patients die when the tumour is malign—not, as a rule, from secondary growths.

SYMPTOMS.

The usual first symptom, although not necessarily so, is a causeless, symptomless bleeding. It may be of bright red blood or it may be dark and intimately mixed with the urine. The patient observes it simply because the urine is coloured. There is no pain or other symptom. Sometimes, on the other hand, pain or frequency of micturition may be first noticed. The bleeding is intermittent, the urine between times being clear. It varies in amount and the quantity is no criterion of the size or nature of the growth, but sometimes the patient states that the blood comes chiefly at the end of the micturitory act and this is of importance. At a later period, cystitis being present, pus may be in the urine and then pain and frequency are complained of. The hæmorrhage may have occurred a year or two before the patient becomes so alarmed as to consult his doctor. The blood may only be present for a day or two and no recurrence of bleeding may take place for months or even for a year. One patient had bleeding for the first time seven years before I saw him and then bleeding at intervals of a year or more. As regards the size of tumours and the quantity of blood, one patient, a female, aged 60 years, had such severe hæmorrhage on several occasions that she was believed to be dying simply from loss of blood, but the tumour was not larger than a filbert, while another patient, a young man, aged 23 years, had the bladder almost filled by multiple papillomatous growths, and yet the bleeding at no time was serious. In early cases where the tumour is small bi-manual examination may give no indication of a tumour, but when the tumour is of large size, and particularly if infiltrating the wall of the bladder, it may be felt by this method of examination. Examination of the urine may be negative, and in my experience, so far as tumour cells are concerned, it usually is negative, but if cells are seen, especially large nucleated cells in groups, the diagnosis of tumour is assisted, but these cells do not necessarily enable you to tell the nature of the growth. The sound is not reliable and [illegible] The cystoscope is invalual[illegible] in many cases to give a pr[illegible] hæmorrhage be present at [illegible] but rarely does, prevent satisfactory examination. Another examination can always be made when the urine is clear or the bleeding less profuse. Strict asepsis is necessary and for the use of the cystoscope three factors are needed—a urethra of sufficient calibre, a clear medium, and a sufficient quantity of solution in the bladder—e.g., four ounces.

PROGNOSIS.

Prognosis depends upon (1) the character of the tumour; (2) its extent, site, and attachment; and (3) the presence or absence of sepsis. This leads me to speak of the nature of the attachment of the tumour. It may be (*a*) pedunculated, (*b*) sessile, or (*c*) infiltrating. The nature of the attachment is very important prognostically and yet unfortunately prognosis cannot always be reliable even if the attachment can be recognised. A tumour with a narrow pedicle may have deep attachments and may invade the mucous membrane for some distance beyond the apparent attachment. In two cases after the removal of pedunculated tumours I have seen very rapid recurrence of the growth. The determination of the likelihood of satisfactory removal is important, as if the tumour cannot probably be excised the bladder should not be opened unless it be to give relief to pain and frequency of micturition or to arrest hæmorrhage. The arrest of hæmorrhage after suprapubic cystotomy in such cases is very remarkable and rapid even when the tumour is very extensive and has been bleeding freely, as the following case shows.

---

[1] THE LANCET, Jan. 5th, 1901, p. 3.

CASE 3.—The patient, whose age was 50 years, had severe and almost continuous bleeding. A large tumour was readily detected on bi-manual examination. Within 24 hours after a suprapubic cystotomy the urine was quite clear and no recurrence took place for weeks, the patient rapidly regaining strength.

TREATMENT.

Palliative measures in the form of drugs are only justifiable when diagnosis has been made and when radical treatment is impossible, but we may consider palliative operative treatment in cases where bleeding or pain and sepsis are undermining the patient's strength.

Operative treatment with a view to removal of the tumour.—The suprapubic route is that of choice wherever the tumour be situated. It gives free access and permits of operation by sight as well as by touch. I think the vertical incision as satisfactory as the transverse, and it has the advantage of weakening the abdominal wall less. If more room be needed the rectus muscle on one or both sides can be divided. Peterson's rectal bag is not required, but Trendelenburg's position is advantageous. The bladder is first distended with fluid, which I prefer to air. No doubt from its weight it causes the bladder in some cases to fall back, but Trendelenburg's posture minimises this, and with fluid distending the bladder when the finger is introduced examination of the wall is easier. Air so quickly escapes that the bladder collapses and examination is not so satisfactory. In exposing the anterior aspect of the bladder the operator should keep close to the symphysis pubis and should open below the reflexion of the peritoneum. It is well to steady the bladder with a double sharp hook, and on incising the wall to make a decided plunge in with a sharp-pointed knife. Whenever the opening is made the finger should be introduced to prevent the solution from escaping. Then the margins of the opening should be caught with Kocher's forceps.

Removal of the tumour with scissors.—The mucous membrane should be snipped around its attachment and then the attachment of the tumour to the bladder-wall should either be snipped through or twisted and torn away gradually. The bleeding, as a rule, is not great, and usually it quickly ceases with hot water injection. I have never had any difficulty with bleeding, but if there was difficulty I would catch the vessels with forceps and leave them *in situ* for 24 or 48 hours. My experience is that satisfactorily to remove the tumour when it is a sessile one is very difficult, but we have at least the satisfaction of knowing that even imperfect removal although not curative yet delays the growth very markedly and prolongs the patient's life. This was well illustrated in Case 1; the operation was performed in 1895 and the patient lived until the end of 1899. The recurrence of bleeding was first noticed one year after operation. If the tumour were favourably situated it would be wise to remove a portion of the whole thickness of the bladder wall.

I demur to any attempts to remove growths per urethram in the female or through small openings, suprapubic or perineal, in the male. Free access must be had and the operator must cut wide of the disease if he possibly can. In two cases I have operated suprapubically after recurrence, the first operation having been per urethram. Both of the suprapubic operations were successful—one eight years ago and the other three years ago—and both were cases of sessile papilloma.

After-treatment.—Primary union should not be aimed at. A tube may be put in and Cathcart's adaptation of the Sprengel pump may be applied. The bladder may thus be kept quite empty and the patient perfectly dry. At the end of 10 days the tube should be removed and the pump should be used only at night. Urine comes generally by the urethra in three weeks, but it may be necessary in the male to pass a bougie to hasten it. There is no objection to the patient sitting up in bed within a day or two after the operation—a matter of much importance in the cases of old persons. I have never had a permanent fistula result, and in only one case, that of a man accustomed to lift heavy weights, have I seen hernia follow the operation, and it was very slight. It came on in one year after the operation.

ENLARGED PROSTATE.

Enlargement of the prostate is so frequently the cause of bladder trouble, producing much discomfort and often great risk to life, that it bulks very largely in our minds as an important disease. To-night I propose to say nothing regarding the etiology or symptomatology but to discuss very shortly the methods of treatment chiefly in vogue at present for coping with the affection.

In the first place I think I may say that it is now generally recognised that to initiate a patient even temporarily into what is termed "catheter life" is a proceeding fraught with much danger and not uncommonly followed by loss of life. Secondly, I think it is also recognised that the chief risk is associated with the occurrence of sepsis, organisms being introduced at the time of catheterisation, and that such an accident may result notwithstanding every precaution which may be taken. Indeed, personally, there is no class of surgical interference which causes me more anxiety than the passage of a catheter for the first time in a case of chronic incomplete retention, as the French term it, or what we know as an over-distended bladder due to enlargement of the prostate. An endeavour should always be made thoroughly to purify our hands and instruments and the meatus and anterior urethra of the patient and to have an area of asepsis around the parts just as in an operation elsewhere when the skin is unbroken. These precautionary measures are imperative, but other questions arise—viz., what catheter should be used? should the bladder be completely emptied? and should any mildly antiseptic solution be introduced after withdrawal of the urine? I would answer these queries thus. Use a red rubber catheter by preference, but if you fail with that use a silver catheter. I advise this primarily because both can be sterilised by boiling or heat. If the bladder be over-distended markedly—i.e., probably the contractile power lost—do not evacuate all the urine at once. If the bladder be not so markedly over-distended and contractile empty it completely but introduce a few ounces of warm boric lotion or boroglycerine in water. A gum elastic catheter is not good as it cannot be purified so certainly as either of the others. French rubber are better. For lubricant a convenient substance is eucalyptus and vaseline (1 in 6) in a collapsible tube. Later—that is, after catheterisation has been used for some time, perhaps by the patient—even if sepsis occur the risk is not so great, particularly if the bladder be contractile. One disadvantage of the continuous use of the red rubber catheter is that increased pain and other symptoms being present, a stone having formed, it may be missed. I therefore in such cases always sound the patient from time to time or use a silver catheter to draw off the urine. Not infrequently I have found the aggravated symptoms to be due to a stone.

A difficulty may arise after a time in the passage of the instrument and operative interference may be necessitated. Or it may be that a patient comes before us with such symptoms that something more than catheterisation is indicated. Many procedures have been advocated, but at present I think that only three hold the field—(1) castration and modified procedures based on the same theoretical grounds, vasectomy, and angio-neurectomy; (2) drainage, suprapubic or perineal; and (3) suprapubic prostatectomy.

I need not detain you with an account of the theory of castration, and I think it will be admitted by all from the large number of successful cases which have been brought before the profession from time to time that this operation is frequently most valuable. I do not trouble you with statistics further than to say that in the most recent paper with which I am acquainted[2] a list of 159 cases is given which does not include either White's or Cabot's series. There were 13 deaths, and of 130 in which the result is stated 90 per cent. were improved after operation. Regarding vasectomy Wood gives a series of 193 cases. In 118 cases (67 per cent.) improvement occurred after operation. Statistics are proverbially untrustworthy and I give these figures merely to show that benefit accrues in certain cases after either operation. The mortality is not high, and neither operation *per se* is of any great danger, and in that particular perhaps we have a reason for the quick and somewhat general acceptance of the procedure by the profession. In all probability the benefit derived at first and occasionally very quickly is from decongestion of the prostate, but the continued improvement and return of voluntary power of micturition may be associated with a decreased size of the prostate by atrophy.

---

[2] Wood, in Annals of Surgery, September, 1900.

Now, having admitted so much in favour of the operation, we may ask, Why does it sometimes fail, or why does complete recovery not ensue? I think that the explanation is due to the varying state of the prostate in different patients. Mr. Reginald Harrison classes the enlargement shortly under three heads which I may adopt: (1) enlargement mainly proceeding from blood engorgement (the prostate equal to a mass of erectile tissue); (2) the fibrotic prostate, consisting of a mass or masses of degenerated connective tissue and muscular fibre; and (3) an enlargement due to prostatic tissue resembling an adenoma. Where decongestion alone can diminish the size of the prostate sufficiently then castration should *a priori* be successful. This may apply to the first of the varieties which I have enumerated, but if either of the other two conditions be present then it is not reasonable to expect relief after castration except in so far as decongestion alone can bring it about. It is in this, then, that the great difficulty in treatment of prostatic enlargement obtains. How can the prostatic condition be judged? Rectal examination does not suffice; measurement of the length of the urethra is fallacious; indeed, I know of no plan short of cystotomy by which we can even approximately gauge the state of the prostate. The cystoscope is no doubt often valuable as an aid to diagnosis in prostatic cases, but we cannot even with this tell how much of the enlargement is due to actual increase of prostatic tissue and how much is due to vascular engorgement. We are therefore driven to this position: that in a case of prostatic enlargement requiring something more than catheterisation castration or vasectomy may give benefit but not necessarily, and if we fail to give relief by such means further treatment is required. In giving advice to a patient we are hampered by sentimental considerations which, however, have a distinct influence with the patient and his friends. No doubt this difficulty decreases in proportion to the patient's age, but I have known a patient well over 70 years of age run away from hospital when the suggestion was made that his testes should be removed. This difficulty does not militate against vasectomy so much, but in spite of Mr. Harrison's views on the subject I think we must admit that hitherto success has attended castration more frequently than it has attended vasectomy. Regarding the cases in which it may be unhesitatingly recommended I would say that it is in old men who have had relief by using a catheter for a time but in whom the difficulty of passing an instrument has become increasingly greater. In such cases congestion has probably increased and produced the greater obstruction. Castration, or it may be vasectomy, by causing decongestion may make catheterisation easier and if in addition atrophy of glandular tissue results we may have the need for catheterisation overcome. On the other hand, I am satisfied that in many cases such operations can scarcely be expected to be successful—namely, in those where the fibrotic prostate exists, or where a real tumour, though benign, of the prostate is met with. I show you three specimens removed from such cases, and very briefly I will detail the history of one of the patients.

CASE 4.—The patient, who was 58 years of age, had had for several years difficulty in, and frequency of, micturition. A double vasectomy was performed in November, 1897, but the symptoms increased rather than diminished. He could pass no urine at all naturally. The catheter was required both day and night. The left lobe of the prostate was small, but the right per rectum was very large. I performed a suprapubic cystotomy in November, 1898, and I found a very large right lobe. It was a fibro-adenoma which was easily enucleated. The patient made a good recovery and he does not now require the catheter.

No previous operation had been performed upon either of the other patients, but both had used a catheter for many months and in each hæmaturia was a prominent symptom. In both of these cases a suprapubic prostatectomy was carried out and both patients made excellent recoveries.

I do not dwell upon the advantage of this method in cases complicated by the presence of stone, but I wish to mention certain advantages which to my mind are of importance. 1. The operation immediately relieves the symptoms. 2. By resting the bladder the bleeding ceases and the patient gains much benefit from relief to pain and sleeplessness. 3. It admits of washing out the bladder very efficiently if that be needed. 4. The bladder being at rest it contracts and regains its contractile power and capability of expelling the urine.

The objections which have been urged against the method are: (1) danger to life; (2) imperfect drainage; and (3) that the prostate cannot be wholly removed. Regarding danger to life, such has not been my experience. I have only lost one case—the patient died 19 days after operation, death being due, as far as one could judge at the necropsy, to old-standing nephritis. It is necessary to judge whether when suprapubic cystotomy is performed it is right to proceed to remove the prostate at once or whether it should be done at a second operation when the patient is stronger. There is a disadvantage in delay, as the bladder contracts and operation is not so easy. Still, for the time the patient is relieved from dangerous symptoms and he regains strength.

With Cathcart's adaptation of the Sprengel pump drainage can be most satisfactorily attained. The bladder can be kept empty and the patient be kept dry. It is not necessary to remove the whole of the prostate. The chief cause of difficulty in micturition and in the passage of an instrument is as a rule either an enlarged middle lobe or a lateral lobe irregularly enlarged. Such masses can be removed.

The risk of permanent fistula after suprapubic cystotomy is because the natural canal has not been rendered patent. If the obstruction be removed fistula will not persist

Lastly, in removal of a mass of the prostate it is in many cases easy, if you cut through the mucous membrane covering it, to enucleate a mass with the finger-nail or a periosteum-detacher. The pedunculated middle lobe may have a firm attachment at one point, and this can be safely cut through, as it is fibrous and does not bleed to any extent.

[The lecture was illustrated by numerous specimens, naked-eye and microscopical, and also by instruments.]

DIAGNOSIS AND TREATMENT OF TYPHOID FEVER.[1]

BY R. W. MARSDEN, M.D. VICT., M.R.C.P. LOND.,
MEDICAL SUPERINTENDENT MONSALL FEVER HOSPITAL, NEWTON HEATH, MANCHESTER.

I MUST in the first place express my appreciation of, and thanks for, the honour you have conferred upon me in requesting me to open the discussion this evening upon two important aspects of a very important subject. It is not necessary to mention the endemic prevalence of the disease in large communities, nor its special fatality amongst the adult population, nor its constant epidemic prevalence under certain conditions, in order to emphasise its importance. The advances which have recently been made in our means of diagnosis, in the bacteriology and surgical treatment of some of the complications and sequelæ, in the discovery of an unexpected association with other ailments, as cholelithiasis, and I might add in the attempts to break through an irrational and stereotyped method of treatment,—these facts constitute a sufficient reason for an interchange of opinions and experiences. Unfortunately, I must at the outset apologise for limiting my remarks to certain points in the diagnosis and treatment. The subject is so extensive and affects so many branches of our profession that the reason for limitation is self-evident, and, moreover, the prime object of this evening's meeting is to obtain a discussion participated in by all. I am obliged, therefore, to leave out of consideration that part of it which deals with the differential diagnosis of the various diseases which have been, or are likely to be, mistaken for enteric fever, as well as the specific treatment of many of the complications or sequelæ which are not peculiar to this disease Taking, therefore, the diagnosis of cases of enteric fever we may divide them into two classes, according to whether it is certain or uncertain. A certain diagnosis may be arrived at either by (1) physical signs or (2) specific tests.

1. I take it that a recent acute illness commencing with lassitude, headache, chills, then epistaxis, enlargement of the spleen, a continuous pyrexia, rose spots appearing in successive crops for several days, and each lasting three or four days, with an absence of leucocytosis, and terminating

---

[1] A paper read before the Manchester Medical Society on March 6th, 1901.

by a remittent temperature gradually subsiding after, say, 17 or 18 days, and accompanied by sudden profuse intestinal hæmorrhage or undoubted symptoms of intestinal perforation, or further followed by a definite relapse, such a symptom-group may be with certainty diagnosed as due to enteric fever. I am aware that no symptom is pathognomonic, but such a combination is, I think, about as certain as anything in our uncertain life well can be.

2. As regards the specific tests the isolation of Eberth's bacillus either from the stools or from the rose spots is as yet impracticable, whilst tapping of the spleen is unjustifiable. On the other hand, the serum reaction, performed under definite rules of dilution and time, may be as convincing and certain as any imaginable symptom-group. It cannot be said that the degree of dilution and the rapidity of agglutination forming the time limit, and acting as a basis for such reports as incomplete or doubtful reaction, are matters of no moment to the physician. It has, I believe, been shown that occasionally with a dilution of 1 in 10, and a time limit of one hour, blood from individuals in whom no history or suspicion of enteric fever could be obtained will produce an agglutination sufficient to warrant the report that the reaction is present. In considering a series of about 200 of the most recent cases examined, in 12 instances a doubtful reaction was reported, in all of which the evidence for the possibility of enteric fever was of the most meagre description, and I am strongly of opinion that some of these cases may be examples of the danger I have just mentioned. But unfortunately this is not the only difficulty, for after the discovery of the reaction it was soon observed that the time of its appearance and the rapidity and completeness of agglutination vary enormously. It is therefore necessary to discuss the possible difficulties in its application.

The blood-serum may retain its peculiar power for so long a time that the attack of enteric fever having passed undiagnosed the reaction is obtained and first noticed during a subsequent ailment. In addition, since the injection of typhoid vaccine has been done on a large scale it is well to keep in mind that the reaction has been obtained as long as two years after its administration. In any case one must exclude the possible previous introduction of typhoid toxins into the blood unless the agglutination occurs very rapidly and with a high degree of dilution, though failing this the most certain test is, I think, to obtain an agglutination increasing in rapidity and completeness as the disease progresses. Thus I recently obtained three reports as follows: (1) incomplete reaction on the tenth day; (2) somewhat incomplete on the seventeenth day; and (3) Widal reaction on the twenty-ninth day. The exact terms are, of course, the result of a standard set up by the manipulator, but the course undoubtedly shows a gradual change in the power of the serum, which is only consistent with the view of a progressive introduction of typhoid toxins into the system, and under such circumstances, where the disease is under observation and the change well marked, warrants with certainty the diagnosis of typhoid fever.

I have already mentioned that the time of the appearance in the serum of the power of agglutinating recent cultures of Eberth's bacillus varies greatly, but it was early discovered that the later in the attack the blood is examined the fewer are the percentage of failures, so that if it be taken at the end or during early convalescence this percentage is reduced to a minimum. I might here refer to the results of the blood examinations made during the last 12 months. Out of 214 cases a positive reaction in 149 instances was obtained at periods varying from the fourth day to the fifth or sixth week, and in this series the clinical evidence was in agreement, whilst in other 11 cases the illness was quite over. In nine instances the clinical evidence was indefinite and the serum reaction doubtful. In 22 instances the clinical evidence negatived typhoid fever and there was an absence of the Widal reaction. Of 18 cases in which the clinical course or a post-mortem examination allowed one definitely to diagnose typhoid fever, in 10 an incomplete reaction was obtained at periods varying from the eighth day to the end of the third week. In another of these cases the reaction was incomplete on the fourth day of illness, two others gave a negative reaction on the sixth and tenth days, whilst other two were incomplete and doubtful after nine and 12 days. The last case died a few days later from intestinal perforation and at the post-mortem examination there were several typhoid ulcerations in the ileum. Completing the 18 cases, there was one instance in which an incomplete reaction was obtained after 10 days and a positive after 16 days, whilst there were two cases where the reaction was negative at the end of two weeks and positive at the end of a month, but in each instance the patient was through the primary attack at the time the positive reaction was obtained.

To complete the 214 examinations, on two occasions a positive reaction was shown which referred probably to a previous illness, since one of these was proved later to have been a case of typhus fever, and in the other there was no acute fever at the time, but seven weeks before the patient had suffered from "influenza." There were also three instances in which the blood gave an incomplete reaction, but the clinical examination was against the view of an attack of typhoid fever.

Summarising the results one finds that of the 214 cases in 209 instances the clinical evidence and the blood reaction were either in agreement or not at variance. It must, however, be noted that in the 149 cases first mentioned where the reaction was positive there were a large number in which the clinical symptoms or history would not have allowed a definite conclusion, and it would be difficult to over-estimate the value of the serum reaction in recognising the existence of a previous or recent attack of enteric fever, as well as its co-existence along with symptoms of another ailment. On the other hand, one has to admit that an incomplete reaction is not unfrequently most confusing and should, I think, be appreciated at something like the value of Ehrlich's diazo-reaction—that is to say, belief or discredit must be attached to it according to the clinical manifestations. Then, again, it is found that in a fair percentage of the cases the serum reaction may remain indefinite or even negative for the first 10 days or fortnight, and that occasionally the positive result may not be obtained until towards the end or possibly after the completion of the primary attack, so that, as in the case I have cited, it is quite possible for death to take place from enteric fever without having obtained a definite Widal reaction, though the blood has been examined only a short time before. Still, if the blood be examined periodically throughout the course of the disease one has to admit that the greater danger is not that the reaction will not be obtained in a case of enteric fever, but rather that evidences of its presence will be obtained in people suffering from other ailments. In most cases this is evidently the least important or least serious of the difficulties. I think one may therefore summarise the position of the Wida reaction somewhat as follows: a negative result, say, at th end of the first week of illness indicates at most a probabilit against the diagnosis of enteric fever, whilst each succeedin negative result increases this probability, so that by the en of the attack a negative result almost amounts to a certaint against the diagnosis. In fact, in all cases in which, as convalescence from the illness is approaching, or in which, afte there has been a continuous fever of about three week duration, the serum reaction is still found negative, I shoul say that the diagnosis of enteric fever must be abandone unless the physical signs form such a symptom-group as have already referred to. I would even go further an include the occurrence of an incomplete and doubtfu reaction obtained by the serum from a case at the beginnin of convalescence, especially if the same result had bee noted during the acute stage of the illness.

Except in very unusual circumstances the diagnosis of enteric fever must always be uncertain during the first week of illness. However strong the probability may be until the presence of a well-marked Widal reaction, when the serum is tested for the first time, or the development of such signs as rose spots, intestinal hæmorrhage, &c., it is evident that without such indications the essential element for making a certain diagnosis must be considered as wanting. Of course, strong probabilities may be obtained where it is known that the individual has been exposed to infection or where other undoubted cases have arisen in the same family. I trust that I shall not be convicted of platitudinism when I lay stress on the necessity of suspecting enteric fever in any acute illness of a week or more in duration which is characterised by indefiniteness of symptoms to physical examination, and especially if the onset is gradual and is accompanied by headache, weariness, languor, feelings of chilliness, and enlargement of the spleen. In this connexion I should like to lay special importance upon the enlargement of the spleen, as in the few cases in which I have been consulted at the beginning of the attack it has seemed to me that the chief increase in bulk has already taken place before the illness is far advanced. Then, again, with the presence during the early period of Ehrlich's diazo reaction in the urine, one may in conjunction [illegible] asles, acute tuberculosis, &c., [illegible] fever, though I think the fact that this reaction can be obtained in other diseases will always militate against any reliance being placed on the test, no matter how regular may be its appearance, in the earlier stages of enteric fever.

The indefiniteness of the symptoms which characterise the early stage of the disease and which is responsible for the frequent diagnosis of influenza and bronchitis may, on the other hand, be continued even throughout the attack. A person complains of lassitude, disinclination for work, and loss of appetite. The thermometer reveals the presence of a pyrexia which may be slight and either remittent or continuous. There may or may not be abdominal symptoms and signs of bronchitis. Such a condition may last for a variable number of days, and even weeks, and be unaccompanied by more [illegible] and [illegible] mild. [illegible] more [illegible] In them also not only are the rose spots absent in a larger proportion of the cases, but even when they occur they are often smaller and more readily overlooked; and again shorter attacks with the temperature of a remittent type are more frequent, or cerebral symptoms, such as irritability, possibly with retraction of the head, somnolence, constant moaning, and even temporary strabismus, may overshadow everything else, the abdominal or respiratory symptoms being so slight that the thought of enteric fever is never entertained. In all such cases, and speaking generally in all doubtful cases, it must be admitted that the value of the serum test, with the reservations which I have already mentioned, cannot be too highly rated. Again, there is the exceedingly interesting apyrexial form of enteric fever, but here I think that unless rose spots were present in crops over a number of days, or unless the Widal reaction were found to increase in power as the disease advanced, an unquestionably positive diagnosis would not be justifiable without post-mortem evidence. Then there is the condition of typhoid septicæmia, when the exact cause can only be determined by bacteriological investigation.

Difficulties in diagnosis may arise, however, not from the indefiniteness of the symptoms, but from their special localisation when the brunt of the infection has an unusual disposition. Thus the symptoms may be clearly and solely those of meningitis, pneumonia, nephritis, cystitis, or cholecystitis until the further progress of the disease brings with it more characteristic signs, or the development of the Widal reaction or a bacteriological examination discloses the exact cause. Occasionally under these circumstances a suspicion of enteric fever may arise where a connexion with previous cases can be traced, but in the absence of such indications the true nature may never be suspected until the bacteriological investigation reveals the etiological factor, for even post mortem the distinctive signs of enteric fever may be absent.

Concluding, then, the question of the diagnosis of enteric fever I would say that clinically, despite the occasional record of rose spots in other diseases, such as the case of acute tuberculosis recorded by Fagge in his "System of Medicine," the only sign upon which absolute reliance can be placed is the appearance of rose spots on several consecutive days either during a primary attack of a continuous fever at least 17 or 18 days in duration, or during a relapse, though I think that an otherwise similar attack accompanied by temporary enlargement of the spleen or intestinal hæmorrhage, &c., would require very clear bacteriological evidence to prove its non-typhoid nature.

Treatment.—Turning now to the treatment of enteric fever I do not propose to question the advisability of confining the patient to bed from the earliest possible moment and keeping him there throughout the attack and for the first 10 days of convalescence. Nor do I think a difference can arise as to the importance of the general hygiene of the sick-room or the necessity for good nursing. Again, I shall not attempt to discuss such very questionable treatment as the use of antiseptic and even vaunted specific drugs, and my own experience has unfortunately caused me to conclude that no benefit is to be expected from the typhoid antitoxin hitherto prepared. Further, we shall probably gain nothing by considering the various remedies which have been used in the treatment of the different symptoms. On the other hand, not only is diet admittedly a most important factor, but comparatively recently attempts have been made to modify or to alter long-established rules.

Even in the most recent text-books we are taught that irrespective of the condition of the patient and his apparent fitness, and ignoring the type of his attack, we must not allow solid food, not only during the acute stage, but till his temperature has been normal for 10 days. Personally, I think it is impossible to have treated many cases without being struck with the hardships of such a rule in some and with its impracticability in others. In the first place we shall doubtless agree that so long as the tongue is dry or the patient from his mental or general condition has no inclination for, or ability to consume, anything beyond fluids, we cannot do better than keep to a rigid liquid dietary, and the advisability under these circumstances of regular administration, limited quantities, and free dilution, along with periodical inspection of the stools, is not in question. But apart from such cases I wish to maintain that each patient should be dieted according to his condition, so that it may happen that one will receive a limited supply of solid food of a specified character almost throughout the attack, whilst another may not be able to resume solid food until convalescence is far advanced. But as an attempt at construction is often more serviceable than detailed destructive criticism and since I firmly believe in maintaining a definite plan, it will, perhaps, suit our purpose better if I lay down a few rules. I should say, therefore, that (1) in every case the patient is to be put on fluids alone at first and (2) that known easily digestible food only should be allowed until at least three weeks after the termination of the attack. Personally I like very much the gradual change dictated by old-established usage, such as fish, chicken, mutton, and beef, in this rotation and allowing time to observe the effect, or want of effect, of each change. Practically, therefore, the change consists solely in altering the time at which a trial with solid food may be made from the tenth day of convalescence to any period during or after the attack when the patient's wishes and our own examination or experience convince us that the attempt may with benefit be made. A third rule which I would make is that until the end of three weeks of convalescence precautions should be taken to prevent the swallowing of large imperfectly-masticated pieces of meat, &c., and here it must be admitted that the absence of ravenous hunger, from the earlier satisfying of legitimate cravings, is itself one of the best safeguards against an inclination to bolt food. At the same time if the habit is firmly rooted I have combated it by having the meat previously minced or chopped.

The objections raised against any deviation from a fluid diet are as follows:—1. The physiological processes are so altered during the febrile state as to interfere with the proper digestion of other forms of food. In practice I think the patient's wishes can with advantage be consulted to a very large extent, and if one carefully watches the effect I think one has to admit that the presence of fever *per se* does not necessarily prevent the assimilation of various solid foods. 2. A second objection urged is that any other form of diet may irritate the ulcerated and catarrhal bowel. But here again one finds numerous foods, such as underdone or raw meat, white fish, boiled chicken, rice, &c., which are more readily digested and assimilated than the precipitated casein of cow's milk, and it is a matter of experience that in some cases with diarrhœa an improvement is best obtained by an alteration in the dietary. Of course, when speaking of any food [illegible] valescent stages it is to [illegible] paid to the cooking and [illegible] pieces of skin, cartilage, tendon, &c. 3. But perhaps the most constant objection urged is the danger of producing perforation of the bowel owing to undigested particles increasing the catarrhal state or mechanically causing a rupture as they are forced along the intestine. This fear is, I think, always uppermost in the mind of the medical practitioner treating the case, and I can affirm that it is a *bête noire* to the initiated who are under treatment. I am aware that authentic instances are on record, and I well remember the case of a youth who shortly after a Christmas dinner showed symptoms of perforation. But it must be remembered that with one or two exceptions perforation has always been found to be the result of a progressive ulceration or necrosis, and the case which I have just mentioned was no exception to this rule, since at the laparotomy the bowels were free from solid particles, so far as could be seen, and the fæces exuding from the perforation were of the usual soft yellow character, whilst there was nothing suggestive of mechanical injury. Moreover, it must be evident that such an occurrence cannot be brought in question under the rules which I have mentioned. A fourth objection to the too early administration of solid food is the possible production of a temporary fever or even of a definite relapse. I am so heretical as to doubt the existence of a febris carnis, and in this connexion I should say that as sudden and at present unexplained rises in the temperature are relatively common during early convalescence from enteric fever there is always the possibility of their relationship to food being *post* and not *propter*, and I have for some time ceased to make any alteration in the diet solely on account of the supervention of pyrexia, with the result, as I think, that the fever has immediately subsided or pursued its further course quite independently of the food given. Then as regards a relapse. This is generally admitted to be the result of a re-infection, so that it is not rational to assume a definite causal relationship where it occurs immediately after. A more likely suggestion is that since during or after an attack of enteric fever the bile may not unfrequently be crowded with the specific bacilli the administration of solid food by increasing the flow of bile may as a result increase the number of bacilli poured into the intestine and thus be instrumental in producing a relapse. Such a suggestion is, however, purely theoretical, lacking confirmation, and from our ignorance of the nature and causes of a relapse difficult to prove. I am, therefore, of opinion that the adduced objections are not a sufficient warrant for the rigid rules which have till recently fettered us. On the other hand, the increased mental satisfaction and improved bodily constitution which follow a more liberal and varied diet demand that some such alteration as I have suggested should be made. In hospitals, certainly, when dealing with a large number of patients, the change is even more essential, as it tends to do away with that deceit and the smuggling of possibly harmful foods which is only too commonly practised or attempted when the restrictions are rigidly enforced.

In conjunction with an altered dietary, a system of regular immersion in a cold, or rather a tepid, bath during the acute stage of illness is capable of greatly altering the aspect of a ward containing a number of enteric fever patients. At the present time antipyretic drugs for the reduction of temperature are advisedly discouraged, and usually one resorts to some form of hydrotherapy. Cold or tepid sponging or douching and cold or ice packs can be used under all circumstances; the essential factor, however, is that they must be regularly and thoroughly administered. But whenever possible a tepid bath of from 75° to 85° F. is to be preferred. It must be distinctly understood that beyond acting as an excellent hypnotic and stimulant in delirious or wakeful cases no immediate benefit is to be looked for, whilst to be of any real value they must be given regularly as the pyrexia again reaches a certain maximum. A short experience of their use will convince one (1) that they are potent factors in reducing temperature with the diminution of its attendant evils; (2) that the intellect keeps clearer during the disease and stupor is lessened; (3) that they exert a general tonic action on the system—the skin keeps softer and more healthy, the circulation is improved, bronchitis, hypostatic pneumonia, and broncho-pneumonia are less prominent features, whilst headache and insomnia are much relieved, the patient frequently sleeping between successive baths; (4) it will be seen that they retard emaciation and maintain the muscular strength and nutrition; and (5) that they diminish the percentage of patients who die from cardiac failure and asthenia. It has further been shown that by their use the toxicity of the urine is greatly increased. To obtain the best results it is necessary that the baths should be commenced early in the attack.

The next point which I wish to discuss is the question of surgical interference. I shall not refer to such operations as tracheotomy for obstructive laryngitis, drainage of an empyema, &c., but limit myself to the consideration of the abdominal complications. Until comparatively recently it seems to have been fairly generally held that the presence of a severe ulceration of the bowel negatived a laparotomy or operation upon the intestines during the ulcerative stage. Enteric fever has, however, benefited from our advances in surgical procedure, so that one may now say that the existence of ulceration *per se* adds very little risk, and that the chief factor to be considered is the general condition of the patient. Such complications as perforation of the intestine, of the appendix, or of the gall-bladder may and do occur in patients who at the time are not in a fit condition to stand an operation. On the other hand, in a large percentage of the cases at the time of the onset of the symptoms the patient's state is sufficiently satisfactory, but from inability to diagnose these complications until the supervention of more pronounced indications they quickly become hopeless. On this account, though experience on the part of the surgeon is very important, the most essential requirement is an improvement in our means of diagnosis. With this end in view Professor Osler, in an article in THE LANCET on Feb. 9th of this year (p. 386), summarises the various points which should be noted and carefully looked for during an attack of enteric fever, and one cannot help feeling that an accurate record on the lines suggested will furnish most valuable evidence for future guidance and will be the means of materially altering the prognosis of these complications. If one waits for vomiting, or loss of liver dulness, or alteration of the pulse, or any other symptom-group diagnostic of perforation, in a large number of instances the time for operating will have gone by, but by keeping a detailed record of the condition of the abdomen during the attack and carefully noting the onset of the slightest abdominal pain, its character, situation, or persistence, the accompaniment of a rise or fall in the temperature, and the alteration in the distension, rigidity, or mobility on respiration of the abdominal walls, I think one need not despair of yet obtaining very much greater success than has been our lot in the past.

Manchester.

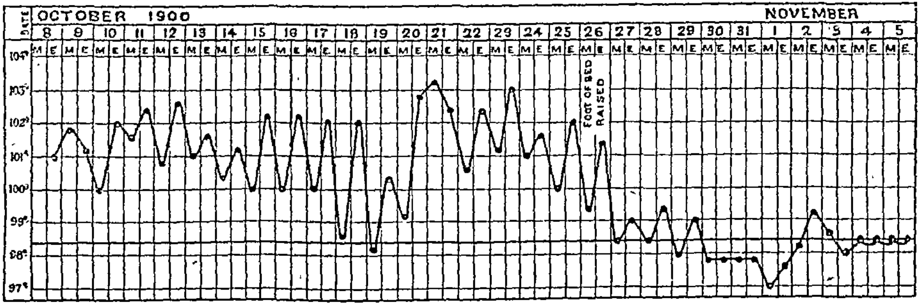
THE TREATMENT OF BRONCHIECTASIS AND OF CHRONIC BRONCHIAL AFFECTIONS BY POSTURE AND BY RESPIRATORY EXERCISES.

BY WILLIAM EWART, M.D. CANTAB., F.R.C.P. LOND.,
SENIOR PHYSICIAN TO ST. GEORGE'S HOSPITAL AND TO THE BELGRAVE HOSPITAL FOR CHILDREN.

THE principle of treatment to be described has a wide range of application in obstructive affections of the respiratory tract. The symptoms produced by a pedunculated growth in the larynx or by a long uvula may be mitigated by position, though the patient is seldom aware of the relief to be obtained from posture alone. In severe chronic catarrh with tenacious expectoration or in the later stages of pulmonary excavation nothing will restrain the patient from flying up into the sitting posture and bending to the struggle as the first of an endless series of coughs ushers in the paroxysm. In phthisis this commonly ends with vomiting as the only adequate mechanism for complete expectoration. Much of all this is avoidable by suitable posture. It is, however, in bronchiectasis that the postural method has its chief application and that its most striking results are witnessed. The following cases, which were exhibited before the Medical Graduates' College and Polyclinic on June 4th, 1901, will speak for themselves.

CASE 1.—The patient, a well-developed and fairly strong girl, 20 years of age, had been subject for many years since an acute pulmonary attack to cough and expectoration which had been worse during the winters, and presented the general characteristics of bronchiectasis. She had never been under any treatment even as an out-patient until she was admitted under my care into St. George's Hospital 18 months ago, having got much worse though she was not bedridden. The complexion was, and had been, habituall slightly dusky, the subcutaneous tissues were full, the vein particularly in the hands, were lax, the finger ends wer considerably clubbed, thickened, and dusky, and the nail were much incurved. Dyspnœa on exertion had been marked symptom. The secretion had been of the typic bronchiectatic character, at times fetid for long periods, i expectoration becoming then more and more difficult an occurring with a gush. Considerable improvement resulte from general treatment in the ward and from the relativ luxury of rest and hospital treatment. The catarrh an expectoration diminished and she was ultimately provide with an automatic respiratory jacket which she wore wit comfort, and at first, she thought, with advantage. Thi did not, however, prevent a return of the symptoms in an aggravated form under the influence of winter weather. On her second admission, on Oct. 8th, 1900, she was suffering from high fever, severe cough, and expectoration. Orthopnœa and the spasms of coughing remained unrelieved in spite of ordinary treatment. The night-sweats and progressive debility caused anxiety lest the septic absorption which was apparently in progress might ultimately prove fatal. While witnessing one of the painful orthopnœic paroxysms of cough it occurred to me that common-sense principles had not been carried out in my treatment. I prevailed upon the patient to lie down, and I raised the foot of the bed to the level of my shoulder. The spasmodic character of the cough ceased at once, the expectoration began to flow easily, and after a few minutes the patient declared herself much relieved. The foot of the bed was now permanently raised by blocks to the height of 14 inches, and the patient has since persevered with this practice. The temperature chart shows that from that date the temperature never rose again.

The sequel of the case is of interest. *The patient was re-admitted on March 26th, 1901, for a return of the catarrh and of the fœtor. From the beginning of the postural treatment the typical expectoration in gushes had ceased, but from time to time the catarrh had become worse and the expectoration occasionally fetid, showing that posture alone will not obviate this result which I suspect may be connected with infection from the mouth. The patient had gained in weight and in strength and the clubbing of the finger ends was perceptibly less than prior to the adoption of the postural treatment. On April 13th several



Temperature chart of Case 1.

arious stumps were extracted. During her stay in the iospital six intravenous injections of protargol were given rithout any striking result. Ichthyol was administered with dvantage and a further instalment of treatment by respiraory exercises was inaugurated. The patient left the hospital nuch improved and, although still rather short of breath ind still expectorating, she is progressing steadily.

The second case is in many points analogous to the other. The patient had never been systematically treated, though he physical signs were clearly those of bronchiectasis.

CASE 2.—A woman, aged 30 years, was admitted in the eventh month [illegible] ind expectorat[illegible] weeks. There was a history of pneumonia and bronchitis at the age of 12 years after getting wet. Since then she had ilways had a cough with expectoration, but she had been worse during the seven months previous to her admission and had been bedridden for six weeks. The paroxysms of cough were exceedingly trying and the expectoration was foul and abundant and difficult to raise. The patient was also permanently orthopnœic, particularly during the fits of coughing. In spite of the complication of pregnancy, which, however, was an inducement to resort to some effective treatment, I determined to adopt the posture method. The patient was made to lie back and the foot of the bed was raised about 12 inches. This gave the first instalment of relief from harassing cough which had been obtained for six weeks. The altered posture was borne without any detriment to the abdominal condition, but after a while there were slight discomfort and dragging from the pelvis. The patient's bed was then raised only for periods of an hour twice or three times a day. Under the administration of ichthyol the progress of the case was most satisfactory, and she was removed to Queen Charlotte's Lying-in Hospital for delivery. The patient was subsequently readmitted to complete the cure and she gained considerably in weight and strength under the combined influence of postural treatment and ichthyol.

The method illustrated by these instances needs no further elucidation. The immediate result in both cases was a great sense of relief, a diminution in the frequency and severity of the cough, a lessening of the sputum, a complete cessation of the gush of expectoration, and presumably the liberation of the affected pulmonary areas from entangling slime and from any further plugging with muco-pus.

The continuous postural method as originally applied in these cases is, I believe, preferable to the intermittent use of posture recommended by Quincke, to whom, as I have lately discovered, belongs priority in the systematic use of *this form of treatment.* *His method, which is to place* the patient in the inclined prone position with the head lower than the feet for a period of half an hour or more night and morning, was described by him[1] in 1898, and was further described by O. Jacobson[2] in 1900. It should not, however, be forgotten that the same principle had long been utilised by some chest physicians, in a modified and perhaps less systematic form, for the relief of the basic cavities apt to occur in phthisis. Patients were sometimes directed to lean over the edge of the bed in order to empty their vomicæ more effectually. This rough-and-ready device is not free from obvious disadvantages and risks and should in all cases find its substitute in that which has been described. Quincke attributes the benefit secured (1) to the mechanical advantage of gravitation, and (2) to the stimulus to cough set up by the progress of the secretion as it reaches healthier and more excitable mucous surfaces, while other advantages are (3) that portions of the lung previously kept airless are enabled to expand, and (4) that the slanting posture by carrying the weight of the abdominal organs upwards against the diaphragm *facilitates expectoration.* A further advantage is that the time of day for emptying the chest can be selected. The various evils of accumulation are obviated or remedied. Local putrid fermentations, ulcerations, and infiltrations, collateral septic broncho-pneumonic infections, and general septic contaminations are all guarded against. Cylindrical bronchiectases are more quickly relieved than the saccular. It is obvious that pulmonary abscesses and empyemata possessing only narrow fistulous communications with the bronchial system are susceptible only of partial benefit. Nevertheless, in a case sent to me for treatment by Mr. Heaton C. Howard of Clapham-road, which proved to be one of pulmonary abscess with secondary empyema and pleuro-pulmonary fistula, great relief was given to the intensely paroxysmal cough, but the case ultimately needed for its cure surgical treatment by incision and drainage.

---

[1] Zeitschrift für Krankenpflege, August, 1898, p. 525.
[2] Berliner Klinische Wochenschrift, Oct. 8th, 1900.

In bronchiectasis the prophylactic capabilities which must belong to this method are evidenced by the immediate results of treatment in the cases reported. The late and destructive results of the affection are entirely due to persistent accumulation and imperfect removal of stale secretion. Had my young patient in Case 1 been seen and treated on this plan several years ago bronchiectasis would never have reached in her the gravity which it now presents. Probably it might have been cured. This result might, indeed, be expected in all growing patients if only timely help could be afforded to the efforts of *naturæ medicatrix*. This points to the urgent need for some more distinctive diagnostic signs to identify the disease at an early stage and these will doubtless be found if sufficient attention be given to the matter.

A cure is perhaps not to be hoped for where fibrous replacement of lung tissue has taken place on a large scale. It is to be feared that in both of the cases mentioned this had already partly taken place and that the persistence of the expectoration and of the catarrh and the recurrence of fœtor are to be accounted for in this way. The obvious indication is sanitation of the cavities which are deprived by the stiffness of their walls of the power of spontaneous evacuation. This is one of the aims of the creosote inhalation method which, however, must be regarded as a somewhat trying and awkward means of effecting the mechanical purpose in view. By enforcing the postural method we have done a great part of our duty towards protecting the patient against any progressive accumulation and its results and we may then without any misgiving take time to select, if necessary, curative measures of greater responsibility whether by the knife, by irritating inhalations, or by injections, all of which methods I have tried in other cases with doubtful benefit.

Where there is no advanced fibrosis, that is in all early cases, particularly before middle age, the best curative treatment appears to me to be a combination of the postural method with well-planned respiratory exercises whereby more and more of the previously hampered lung substance is restored to activity, and most of the space usurped by the dilatations may gradually be reclaimed by healthy pulmonary tissue. The experience in Case 1 demonstrates, however, that the respiratory advantage thus sought is not in itself capable of producing the desired effect so long as the major indication of keeping the cavities empty and dry remains unfulfilled. The wearing of the respiratory jacket as a stimulus to respiration did not make any appreciable difference in the pulmonary condition.

Bronchiectasis, though far from uncommon, is a relatively infrequent occasion for this treatment. But we all have daily opportunities of contributing to the comfort and relief of patients suffering from general catarrhal affections with tenacious mucus Though it is difficult to induce them to lie down after they have been accustomed for days or weeks to struggle with their cough in the sitting posture, if only we can get the shoulders down and the pelvis raised the struggle is at an end and a case of long-standing may in a few hours be on the high road to recovery.

Curzon-street, W.

AN UNDESCRIBED INNOCENT (?) GROWTH OF THE GALL-BLADDER.

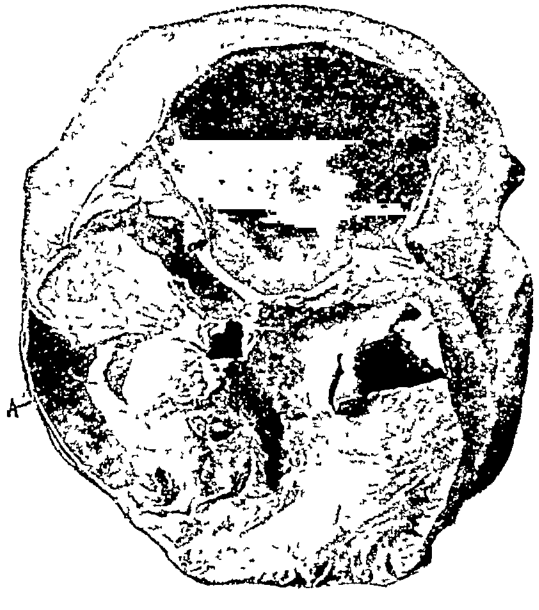
BY E. STANMORE BISHOP, F.R.C.S. ENG.,
HONORARY SURGEON TO THE ANCOATS HOSPITAL, MANCHESTER.

IN all books which treat of pathological changes in the gall-bladder the main interest centres in those produced by the presence of gall-stones, and secondarily, in carcinomatous degenerations. Very few innocent growths have been described. Mr. Mayo Robson says that innocent growth, except of inflammatory origin, is extremely rare; whether the condition figured below comes under that description appears to be doubtful. Papillomatous growths have been described, and in the Hunterian Museum is a specimen (No. 2812) showing villi and papillæ on the mucous surface, but these were associated with, and were apparently due to, the irritation of biliary calculi. In Guy's Hospital Museum papillomata are seen (No. 1404) sessile in some parts, whilst becoming pedunculated in others. It will be seen from the illustration that the condition figured is different in many ways from any previous innocent growth described—at least to that of any which I have been able to find after a fairly comprehensive search.

The case from which these figures were taken is that of a woman, aged 42 years, who was sent to the Ancoats Hospital by Dr. J. E Harburn of Buxton She was a healthy, florid-looking woman, fairly stout and in good condition. She had had no children and no miscarriages. Her periods were, and had always been, regular and never excessive. Previously to the last two years she used to have almost weekly bilious attacks which were never very severe, were attended by transient jaundice. and had since that time entirely disappeared. The last attack of jaundice was eight years ago. 18 months since she began to be conscious of a dull sickly pain, associated with a feeling of weight, not in the epigastrium or right hypochondrium, but in the left lower quadrant of the abdomen and over the sacrum. The pelvis was free. Below the liver, moving with it and with respiration, was a large rounded tumour, the dulness of which on percussion being continuous with that of the hepatic region. There had been no urinary symptoms There was no pain or discomfort in the right shoulder and there was no tenderness on manipulation. The bowels acted regularly and the stools were normal in colour.

On opening the abdomen parallel and internal to the right linea semilunaris the gall-bladder presented It formed a tumour of the size of a child's head, evidently multilocularly cystic, the contents of the cysts showing a bluish colour through the thin walls. There were no adhesions. The tumour was packed around with sponges and the cyst nearest to the surface was tapped. Mucus tinged with bile escaped through the cannula but the swelling was not perceptibly decreased. A second and deeper cyst was tapped through the same orifice with the same result and it became evident that the main bulk was composed of comparatively small cysts having no intercommunication.
The opening in the abdominal wall was then erLot
and the entire mass was turned out of th habitually
sprang from the under surface of the d, the veins,
for a pedicle apparently the cystic duct ver ends were
enlarged by the growth of the tumour y, and the nails
As this was too large to admit of the rtion had been a
constricting ligature, and as it appear en of the typical
attempt at transfixion with ligature in se long periods, its
in leakage of its contents into the genera re difficult and
its walls were carefully sutured all round to ment resulted
toneum and that portion of the mass above the relative
away. A few vessels in the walls of the gall-b catarrh and
ligature, but the bleeding was comparatively y provided
wound was then closed around it as far as wore with
remaining base of the tumour was dressed with io e. This
and the rest of the skin wound was sealed w

FIG. 1.



Growth of gall-bladder: cut surface of base. Rather more than half size.

Fig. 1 shows the growth from the cut surface. Examination of the tumour showed that it was the gall-bladder itself, the cavity of which was divided up by dissepiments into many separate spaces. These, as shown in the illustration, have been opened in order that the cavities might be filled with cotton-wool, so that in setting it might retain its original shape, but originally all the cavities were distinct and had no connexion with one another. They contained mucoid fluid stained with bile. No calculi were present and there were no hydatids.

The after-course of the case threw some little light upon the mode of origin. The stump left in the abdominal wall, composed of some part of the tumour, and the walls of the cystic duct gradually contracted. The actual cautery was applied twice to the centre, and as the contraction went on bile escaped from the lower inner quadrant of the circle, showing that the tumour was not equally connected all round at its innermost extremity. It would appear that it must [illegible]d from the upper wall of the bladder or duct, and [illegible] the process of growth it had blended with the [illegible] and fundus of the gall-bladder; union had not [illegible] complete in the duct itself. Microscopical sections of the septa and walls showed dilated glandular tubes of all degrees. Even the largest cyst-walls were lined by cylindrical epithelium. There had apparently been hypertrophy of the mucous lining of the wall, with immense development and distension of the glandular layer, but what caused such hypertrophy was not so clear. Was this an extreme stage of a papillomatous degeneration or was it a new formation? That it was not a malignant growth seems evident by the regular arrangement of the component tissues and the absence of any confusion between the lining epithelium and the walls upon which they rest. No sarcomatous cells could be seen. Moreover, with the exception of the growth and some slight temporary attacks of jaundice the patient was in perfect health. She had not lost flesh and was of a clear, healthy complexion at the time of operation, nor has she lost ground since. Bile, which is perfectly healthy, still escapes at times from the site of operation and probably a cholecystenterostomy will be required, but otherwise she is perfectly well.

Manchester.

A CASE OF MENINGITIS, PROBABLY INFLUENZAL IN ORIGIN.

BY ARTHUR F. PERIGAL, M.B., CH.B. EDIN.

WHILST holding the appointment of civil surgeon at Dover last summer a tall, well-built corporal, aged 24 years, was admitted under my care into the station hospital suffering from what seemed to be a severe attack of influenza which had begun suddenly on the previous night. There was no account of any serious illness or specific disease and his family history was good. On admission his temperature was 103·6° F. and he complained of pain in the back, the legs, and the head, and especially behind the eyes. There were no signs of pulmonary disease and the urine was normal. He was slightly delirious that night. On the following day his temperature was 102° and he had two attacks of epistaxis. At the end of a week he was improving in every way with the exception of headache, when his temperature went up to 102° and a sharp attack of diarrhœa occurred which continued on and off during the next week, his temperature keeping between 102° and 103°. Although no spots were to be seen and no signs of splenic enlargement or pulmonary disease, a specimen of his blood was sent for examination as typhoid fever was suggested, but Widal's reaction was negative. Early in the third week his temperature suddenly rose to 105° and he developed a [illegible] the right cheek whic[illegible] the nose. This disappeared in three or four days, his temperature gradually dropping to 101°, but he still complained of considerable pain in his head, chiefly in the occipital region; he had no retraction of the neck. Slight diarrhœa continued, his temperature gradually going up to 103°. During the fourth week he had a rigor and his temperature, which had been normal for two days, rose to 103·4°; he became very restless and his headache was worse. The same evening he was semi-comatose; he occasionally threw his arms about and kept on rubbing his head with his hands, and when roused and questioned he looked fairly intelligent but answered gutturally. His eyes were turned upwards and to the left which led me to suspect either an irritative lesion of the right cerebrum or a paralytic lesion of the left cerebrum, but he had then no signs of paresis and was very restless. After sleeping for a few hours he awoke with right hemiplegia and aphasia. The right side of his face was paralysed, but deglutition was unaffected; he passed urine involuntarily. Two days later there was slight improvement; his temperature was 100° and his pulse was good. He spoke a little and moved his right leg occasionally, but his right arm was powerless. Towards night, however, he again became restless and at times comatose; his pupils were widely dilated and insensitive to light and his eyes were turned to the left. Neither muscular twitching nor retraction of the neck was present. When seen next day he was steadily sinking, both arms and both legs being paralysed. In the afternoon he had an attack of hæmatemesis and died two hours later.

As regards treatment, at first the patient responded to the ordinary remedies for influenza, but as time went on and meningitis was suspected his head was shaved and an ice-cap was applied. Phenacetin and caffein (five grains of each) relieved the headache. The other symptoms were treated as they arose and stimulants were given when necessary. Towards the end a catheter was used regularly to prevent over-distension of the bladder.

At the post-mortem examination the brain was found to weigh 54½ ounces; the vessels throughout were enormously congested, especially those on the cortex. The dura mater was thickened and adherent in places where there were patches of organised lymph of the size of a sixpenny-piece, chiefly involving the upper portions of both Rolandic areas and the falx cerebri. On removing the brain a large quantity of serous non-purulent fluid was present at the base, over the whole of which were scattered patches of organised lymph. One of these deposits involved the inter-peduncular space. Though careful search was made no tubercles could be found. On section the brain substance was soft and œdematous; the ventricles, especially the lateral ventricles, were greatly over-distended with serous fluid, similar in character to that at the base. There was no sign of hæmorrhage or thrombosis. The hydrocephalus was evidently due to the occlusion of the foramen of Majendie by organised lymph resulting from meningitis. The cerebellum was soft, but otherwise it was normal. The spinal cord and membranes were normal. The lungs, the kidneys, and the stomach were somewhat congested; all the other organs, including the intestines, were quite normal.

The interest of this case lies in the early symptoms and their sudden onset in a strong, healthy subject, also in the fact that there were other cases of influenza in hospital at the time. Was this a case of influenza terminating in meningitis, or were the early symptoms those of commencing brain affection? Again, supposing the swelling of the face was true erysipelas, would this, considering the possibility of influenza, have been likely to cause meningitis, which apparently is a rare complication of erysipelas?

New Barnet.

THREE UNUSUAL CASES OF CEREBRO-SPINAL FEVER.

BY W. J. BUCHANAN, B.A., M.B. DUB.,
MAJOR, I.M.S.; SUPERINTENDENT, CENTRAL PRISON, BHAGALPUR, BENGAL.

THE following three cases of cerebro-spinal meningitis, which have been met with recently in the course of a persistent outbreak, have some points of special interest. In the first case there is the joint affection which appeared before the cerebral symptoms; in the second case there are the symptoms of hemiplegia; and in the third case the intensity of the process was such that the cerebellum was infiltrated with blood.

In the past four years there have been 60 cases of cerebro-spinal fever in the Bhagalpur Central Prison, and a detailed account of certain new points in the etiology of the disease as evidenced in these outbreaks has lately appeared.[1]

CASE 1. *Cerebro-spinal fever with arthritic complications.*—A Hindu, aged 40 years, who had been about six weeks in prison, working as a repairer of roads, was admitted to hospital with a temperature of 102° F., complaining of pains in the joints. The tongue was coated and the eyes were congested. At first he appeared to be suffering from subacute joint rheumatism, as both knees, both ankles, and the right wrist were much swollen and painful. The temperature remained at about 102°. The patient gradually became unconscious, and lay on his side with his knees drawn up. Retention of urine and involuntary passage of stools followed. Kernig's sign could not be elicited on account of the swollen condition of the joints. He died on the sixth day. There was no previous history of rheumatism. At the necropsy, 10 hours after death, rigor mortis was well marked. The lungs were deeply congested, but there was no pneumonia. A few old pleural adhesions were found at both apices. The heart was healthy, as were also the other organs, except the brain, which weighed 49 ounces. On its upper surface there was a very large amount of greenish-yellow exudation in the sulci; this extended to both sid and also backward to the fissure of the cerebellum whic was blocked with this greenish purulent exudation. Th base of the brain in this case escaped. There was muc turbid fluid in the lateral ventricles and in the spinal cana The joints were much swollen and full of flaky, yellow, oi fluid.

CASE 2. *Cerebro-spinal fever with hemiplegia.*—Th patient was a feeble old Mahomedan, aged 55 years his height was 5 feet 1 inch, and he weighed only 9 pounds. There was no history or sign of syphilis. H was brought to hospital from the sleeping barrack in state of paralysis and aphasia. Hemiplegia of the right sid was found; the tongue protruded to the right side. Thoug the patient could not speak he appeared to understan questions. His temperature on admission was 102° F. an during the six days of his illness it fluctuated from 101° t 102°. The pulse was small and usually rapid, but it vari in a characteristic manner from 80 to 110. Puffing respira tions came on during the last day. The motor aphasia wa well marked from the first day, but whether the other centr concerned in voluntary speech were affected it was im possible to find out owing to the ignorance of the patien Herpes appeared on the right side of the upper lip o the second day before death. There was also bladde paralysis. Babinski's phenomenon was also elicited. A the necropsy thick yellow, fibrinous exudation was found i abundance over the upper surfaces of both hemispheres o the brain. This was especially thick and almost gelatino over the left side, including Broca's convolution; it al passed back as far as the fissure of the cerebellum. Ther was no hæmorrhage in any part of the brain. The cerebr spinal fluid was very turbid and turbid fluid was also foun in the lateral ventricles. The brain weighed 51 ounces—a unusual weight for so small a man. The only other featur of interest in the necropsy was a well-developed Meckel diverticulum, four and a half inches long, projecting from th lower part of the ileum.

CASE 3. *Cerebro-spinal fever of fulminant hæmor rhagic type.*—A man, aged 45 years, had worked a day and took his food at 6 P.M. Shortly afte taking food he vomited and quickly became uncon scious. The breathing rapidly became stertorous; th pupils were dilated. When seen by me, an hour after th attack, Kernig's symptom was extremely well marked in bot knees. The patient died in three and a half hours. At th necropsy, 10 hours after death, the dura mater was found t be intensely congested. The surface of the brain was con gested to a degree that I have never before seen equalled The sulci were filled with a fine cloudy lepto-meningitis. O cutting into the brain it could not be described as other tha infiltrated with blood-clot. The fluid in the spinal cana looked like almost pure blood. The other organs presented nothing abnormal, except that both of the lungs were deeply congested. Several tubes of the cerebro-spinal fluid were taken and sent to the Research Laboratory, Bombay, fo examination, and in the fluid there was found the diplococcu intracellularis of Weichelbaum. The heart weighed no les than 12 ounces free of all clots.

REMARKS.

I have had special opportunity of studying this disease i the 60 cases which have occurred here in the past four years Of these 60 cases 43 were fatal, giving a mortality of 71 per cent., which is high even for this fatal disease. Of the 43 fatal cases 22 were of the fulminant type, causing death in one or two days. 17 cases were acute, the patients dying in from three to 14 days. Four cases were chronic, lasting from two to three weeks. Most cases occurred between the ages of 30 and 45 years. Pathologically the cases may roughly be divided into two classes: (1) the posterior basic, and (2) the vertical. In the posterior basic form the purulent exudation is chiefly confined to the base of the brain and medulla, and extends for varying distances down the cord. In the vertical cases the exudation is found filling up the sulci on the upper surface of the hemispheres, but in some cases it extends down the sides and back to involve the cerebellum.

Speaking generally, the characteristic signs of neck retraction and neck pain are found in the posterior basic cases and severe frontal headache in the vertical cases, but this rule is by no means absolute. In one recent case, a vertical one, I have found Babinski's phenomenon, which I understand to be extension instead of flexion of the toes on tickling the

---

[1] Journal of Hygiene, No. 2, April, 1901, p. 214.

les of the foot. I had not searched for it in the other ses.

In Case 1 the arthritis is of interest It is a sym- om which has been known from the earliest records of e disease,[2] and has recently been written about by Dr ouncilman and Dr Osler As the latter writer says[3] it is a very inconstant symptom" I have only found it ree or four times in these 60 cases In the epidemic *Boston it was found only six times in 111 cases* se 2 is remarkable on account of the prominence of the miplegic symptoms Various paralyses are not uncommon, t in the 111 cases of the outbreak at Boston there were ly two cases of hemiplegia. Case 3 was of a type which have not been able to find described elsewhere The tense nature of the congestion and the hæmorrhagic filtration of the brain were unique in my experience To ake sure that I was correct in regarding it as a case of rebro-spinal fever I had the fluid examined in the Bombay search Laboratory and the diplococcus intracellularis of eichelbaum was found.

The rarity of this disease in England is remarkable. Except Liverpool, Manchester, and Bristol I do not remember y cases being reported in England save on a training- ip In Ireland, on the continent, and in America the sease is well known In India the disease has been cognised for 20 years past It is probable that it is the rity of the disease in England which accounts for the *perfect descriptions of the affection in most modern* glish text-books Even in an otherwise very admirable Text-book of Medicine," published in April last, the scription of the disease is utterly meagre and behind the nes The standard monograph on cerebro-spinal fever is e report to the Boston Board of Health by Dr Councilman, Mallory, and Dr Wright

CASE OF RENAL COLIC WITH UNUSUAL SYMPTOMS.

BY O CORBEN, M R C S ENG, L R C P. LOND,

AND

J OROPPER, M A, M B, B C CANTAB

A MARRIED woman, aged 30 years, was first seen by r Corben on March 14th, 1901, and was then complaining pain in the right side extending downwards from the wer ribs, there being a good deal of tenderness over the ole right side of the abdomen The pain, though great at nes, was not typical of renal calculus The patient was idently very ill and of an unhealthy sallow colour and ffy in the face, suggesting nephritis, but there was no ver and the urine was normal She was much constipated. was impossible owing to great tenderness, absence of fever the possibility of appen- be dismissed. She was given a mixture sulphate of magnesia and tincture of opium and put milk diet The urine was found later to have a nt cloud of albumin and to contain squamous epi- lium When seen a few days later the patient seemed much better that a tonic was ordered In a few days, wever, the symptoms were again so much aggravated that urgent message was sent After this date on two casions a temperature of 102° F was recorded. A thermo- ter was left with the person acting as nurse, but no other e of temperature was reported to us On account of the tance a daily visit was impossible

About this date the pain was complained of as radiating wards and backwards over the right scapula, and there was ood deal of catching of the breath, as in pleurisy Neither liver nor the kidney could be felt, but there was slight elling over the lower ribs, as seen from behind Constipa- n still persisted On March 29th borocitrate of magnesia s given in drachm doses every morning On the 30th re were a good deal of cough and hæmoptysis, the ttom of the chami e pain in the side tient was seen in s but the breath was very foul The diagnosis was very ubtful, and we had to consider tuberculous renal disease, bdiaphragmatic and hepatic abscess renal calculus, &c, *though most of these seemed* to be excluded by at least some of the facts of the case In order to clear the matter up specimens of the urine and sputum were forwarded to the Clinical Research Association, from whom the report on the urine was as follows. "Acid, specific gravity 1008, albumin a trace, a fair quantity of deposit, consisting of pus with many large squamous epithelial cells and a few red-blood discs No casts or renal cells" The report on the sputum *was very doubtful as to the presence of tubercle.* On examination of the right side of the chest moist sounds were heard at the right base, the percussion note was slightly but definitely impaired, but without any signs of consolidation The matter, however, was cleared up by the passage on April 2nd of several very sharp fragments of urate stone, about 10 in all, the original stone having been nearly a quarter of an inch in diameter The patient seemed much relieved after this, until April 15th when nine more pieces of stone were passed similar to the first Curiously enough, since this date the patient has frequently had quite typical attacks of renal colic She has, however, improved in health, though from April 7th to 26th she noticed blood in her urine A specimen sent on April 2nd showed distinctly the presence of blood, being more than smoky There was also slight sediment of pus On the 27th the urine was normal She was given 10 grains of salol every morning The pain on the 30th only occurred at times and the patient was able to be downstairs and to do some, if not all, *of her usual work* On May 12th *she was looking* and feeling well She occasionally has pain across "the small of the back" and at times a little pain on passing urine, but the specific gravity of her urine is 1018, it is acid, free from albumin, and without deposit on standing

PUERPERAL ECLAMPSIA: FOUR CASES SUCCESSFULLY TREATED BY RECTAL *INJECTIONS OF CHLORAL* HYDRATE.

BY WILLIAM BOURNE HALLOWES, L R C P, L M, L.R C S IREL,

SURGEON TO NEWARK HOSPITAL, CERTIFYING FACTORY SURGEON FOR NEWARK AND DISTRICT, MEDICAL OFFICER TO THE POST OFFICE

I HAVE read with great interest the very instructive article *by Dr Robert Jardine on the above subject which appeared* in THE LANCET of June 15th, p 1682 Having had four cases of eclampsia in somewhat over 2000 labours, all of which terminated favourably under rectal injections of chloral hydrate, I venture to think that a brief account of the same may be of interest, and perhaps of help, to my brethren engaged in general practice Of course, I am fully aware that there is nothing new or original in this line of treatment, I simply followed the advice given in Swaine's "Obstetric Aphorisms" which I hurriedly consulted on the appearance of my first case many years ago But where we find opinions so widely divergent, and more especially amongst those to whom we look for guidance, as to the pathology and *fons et origo mali* of this terrible complication, it almost becomes the duty of those who have fortunately been successful in adopting a special line of treatment to place that success on record, although limited, as in my experience, *to four cases* All four cases were primiparæ, two commenced ante-partum and two post-partum, one ante-partum and one post-partum were illegitimate In all four cases the convulsions were severe and of fairly frequent occurrence. Blood letting (20 ounces) was tried in one case (post-partum) after consultation, but without effect. On the continuance of the convulsions 60 grains of chloral hydrate in one ounce of water were injected per rectum; this was repeated three times during the next 12 hours, on the slightest reappearance of "twitching," recovery being afterwards *uneventful* In the other post partum case (illegitimate) the same treatment was adopted The attacks were severe, but readily yielded to the influence of the chloral. It was however, necessary to administer in all four injections, at intervals as occasion required, for 20 hours following delivery Chloroform was administered in one case (illegitimate), ante partum, pending the dilatation of the os Unfortunately the supply ran short and during my brief absence to obtain some more and the assistance of a brother practitioner, the patient "had a most awful attack," to use the words of her mother, who on my return handed to me on a plate the two lower central incisors, which had been forced completely out of their sockets by the violence of a convulsive seizure. Chloroform was at once given by my colleague, digital dilatation of the os was employed with care, with podalic version, and delivery was completed as soon as possible. Convulsions recurred in about an hour, and immediately 60 grains of chloral were administered as before described. This induced complete cessation for more than an hour, then a slight return was manifested and the injection was repeated, which had a most beneficial and lasting effect, the patient passing into a sound sleep lasting for several hours. It was, however, necessary to repeat the chloral three times at intervals of from three to four hours. Subsequently convalescence was uninterrupted. In this case the patient was unconscious after delivery for quite 24 hours. In the other ante-partum case the patient suffered from severe bronchial catarrh, so that it was impossible to administer chloroform; but fortunately the labour was fairly well advanced, and two injections, at an interval of about one and a quarter hours, sufficed to stave off further attacks before delivering with the forceps. Subsequently three injections were required and immediately given on the first sign of recurrence, at intervals gradually lengthening to three, four, and five hours, after which recovery was normal and complete.

All my cases were at or about full-term. In such ante-partum cases I would expedite delivery by all legitimate means without being unduly meddlesome. In ante-partum or post-partum cases I would say, Keep the patient from the exhaustive effects of the eclamptic seizures, prevent them from coming on, stand by, and act promptly. I have had no experience of this complication in the earlier months of pregnancy, but should such an emergency arise and remedial measures fail to arrest the onset of these deadly attacks I should feel it my duty to induce premature labour, taking good care to do so before the patient's strength had become exhausted.

Newark, Notts.

A CASE OF INTESTINAL ADHESIONS SIMULATING TUMOUR FORMATION,

AND CAUSING A RISK THAT THE SURGEON MIGHT TAP THE BOWEL UNWITTINGLY.

BY JOHN D. MALCOLM, M.B., F.R.C.S. EDIN.,
SURGEON TO THE SAMARITAN FREE HOSPITAL.

ON Jan. 7th, 1901, Mr. S. Parsons Smith of Croydon asked me to see a patient, 45 years of age, from whose abdomen large quantities of clear fluid had been drawn off from time to time during a period of 18 months. The peritoneum was distended, the legs and lower parts of the body were extremely œdematous, and the patient was unable to assume the horizontal position without inducing dyspnœa. Vaginal examination showed that the pelvic contents were fixed. We drew off some pints of fluid by means of an aspirator, the puncture being made near the umbilicus. When the fluid was removed there remained a firm, hard mass which appeared to rise out of the pelvis, and which I believed was most probably a malignant growth.

I was asked to see the patient a second time on June 4th. In the interval she had been better; she had been almost free from œdema and had been able to walk about. She was again greatly distended by fluid in the peritoneum and in the tissues of the legs and lower part of the body. Although larger in the abdomen she seemed to me to be stronger than she had been when I saw her in January and the pulse was of better character. I recommended that an exploratory incision should be made to enable us to ascertain exactly the nature of the intra-peritoneal condition and to decide whether it was possible to help the patient by surgical means.

On June 6th Mr. G. E. Newby anæsthetised the patient and I made a short incision on the left of the umbilicus by which I let out four or five quarts of serous fluid and a great quantity of white flaky lymph. When the bulk of the fluid had escaped a smooth, reddish, rounded mass was seen filling the lower part of the abdominal cavity. On palpation this seemed to be a cyst and with the finger I felt that the front of the mass was continuous with the peritoneal lining of the anterior abdominal wall a little above the level of the pubes. The condition was very like that which is found when a broad ligament tumour raises the pelvic peritoneum high up into the abdomen. At first there seemed to be no doubt that the next step in our investigations should be the puncturing of the cyst-like mass with an aspirating needle. I noted, however, that there were no intestines visible above the supposed tumour and when the fluid was more fully removed th intestines were still not discovered. On percussing the tumour-like mass I found that it was resonant and there was then no doubt that it consisted of intestines matted together by adhesions. I washed out the cavity, removing as much of the loosely adherent lymph as I could, and closed the incision, leaving a drainage-tube in its lower end. After a fortnight the wound was healed except where a small drainage-tube passed through it. There was no elevation of temperature and the patient took food well and slept well. Mr. Smith informed me on June 30th that th "œdema had disappeared. The drainage-tube was ac well in allowing escape externally of the fluid. The patien continued to improve in general health and was able to from bed to sitting room."

I have described the mass of intestine as being in the lower part of the abdominal cavity. This position wa however, to some extent more apparent than real. Th fluid had accumulated in the upper part of the peritoneal sac and had pressed the bowels downwards, but the enlargement of the cavity upwards made the tumour-like appear to be relatively lower. I noted before the operat was finished that the upper walls of the abdomen had down towards the bowels to a considerable extent and the operation the intestines have expanded and have assu a fairly normal position.

I was aided in this operation by the fact that 15 years I was an onlooker when a somewhat similar condition discovered. The mass of intestine was enveloped in adh omentum and was even more prominent and rounded and a tumour than in my case. I noted, however, in that also that the *intestines did not* show themselves above supposed new growth. A trocar was inserted into the and when I saw only a little yellow fluid escaping from cannula I at once recognised that the intestine had punctured. Again, a friend to whom I mentioned the now recorded has told me that he had been present a operation when a similar mass of intestine was cut i its nature having been unrecognised until the bowel opened.

If the possibility of the existence of the condit described above is known and suspected a correct diagn is easily made. The absence of the intestines above supposed growth and the resonance of the latter on cussion are conclusive. If, however, the nature of the dition is not recognised the surgeon is almost certain make a mistake which may very probably prove fatal to patient. I hope that the publication of these notes, drawing attention to the difficulty, may possibly save s surgeon and patient from such a disaster.

Portman-street, W.

OBSERVATIONS UPON 40 CONSEC CASES OF INTUBATION OF THE LARYNX IN DIPHTHERIA.

BY CONRAD BASAN, M.D. BRUX.,
ASSISTANT MEDICAL OFFICER AT THE EASTERN HOSPITAL,
HOMERTON, N.E.

INTUBATION of the larynx is by no means a t diff operation, and that it is successful in diphtheritic the table given below sufficiently demonstrate th its introduction into the diphtheria wards of th Hospital I have given it a fairly extensive trac cases an excluding those cases in which it was at this rule intubation was tried before having recours ertical one, Diphtheria antitoxin was also freely adminis derstand of the success in these cases is due to its ickling th at the outset that the operation was the anatomical knowledge possessed by a student, combined with a little manual dexterity that can be acquired by practising upon the cadaver, is all that is necessary, albeit there are difficulties in the living that cannot be learned otherwise than by experience. But in spite of the patient's temporary struggles [illegible] practice. The instruments used at the Eastern Hospital were supplied by Collin of Paris. Compared with the ordinary O'Dwyer's the tubes are lightly made, shorter, and the fusiform swelling of the body shades off above and below less abruptly. The obturator is jointed as usual, but the upper extremity has a horizontal slit, into which the end of the sliding catch of the introducer fits. This is in every way satisfactory, it locks safely and is not iable to get out of order.

The results of the 40 consecutive cases I have intubated re set out in the following table.

—	Number of cases.	Recovered.	Died.
ntubation alone	32	28	4
ntubation with subsequent tracheotomy	8	5	3
Total	40	33	7

The ages ranged from 13 months to seven years; e youngest recovery was 18 months. Of the eight [illegible] intubation four patients had membrane in [illegible] of these died from broncho-pneumonia; [illegible] as that of a child with an impermeable [illegible] stenosis of the larynx following upon ntubation who succumbed to a relapse of diphtheria some nonths later. Of the four cases of death after intubation lone three were hopeless diphtheria cases. Two of these atients died completely relieved of the obstruction, with the ibe in the larynx. The other patient developed scarlet ever two days after admission; and although she had [illegible] om the laryngeal obstruction a brawny [illegible] of the neck set in, with otorrhœa and [illegible] and she died 22 days after admission. [illegible] ne post-mortem notes of one of my cases [illegible] died with the tube in the larynx.

[illegible] The patient was a girl, aged 13 months, who was dmitted to hospital on Feb. 22nd, 1901, at 3.40 P.M., and who ied on the 23rd at 1.20 P.M. A post-mortem examination was nade on the 24th. The tonsils, uvula, soft palate (anterior nd posterior surfaces), and lateral walls of the pharynx were overed with greyish-black membrane; the tissues were somewhat swollen and injected. A No. 2 intubation tube was within the larynx and its lower opening reached to the pper border of the fourth tracheal ring, the tube was lear, the metal was bright, and there were no signs of njury to the supra- and intra-laryngeal tissues. Membrane ad completely invested the epiglottis, the aryteno-epiglotdean folds, the interior of the larynx, the trachea, and the ght and left bronchi and their ramifications as far as they ere traced. The visceral pleura covering the lower lobe of e right lung was smeared with recent lymph. The lobe as dark and heavy; on section it was red, granular, friable, nd pieces of it readily sank in water. The ramifications of e bronchus were lined with easily detachable tubes of membrane. The left lung was dark and spongy, and on section showed similar tubes of membrane. Further examination s not allowed.

Of the 28 recoveries after intubation alone membrane ughed up through the tube was expectorated in five cases. ppend the notes of two of these by way of illustration *de* Cases 2 and 3) referring to another later (*vide* Case 5).

ASE 2.—A girl, aged six and a half years, was admitted ospital on March 8th, 1900, at 1.40 P.M., with faucial heria and urgent croup. Intubation at once gave full [illegible] On the 9th, 16 hours after admission, the became very restless, her lips were cyanosed, and some retraction of the chest. The patient soundly throughout the night and was now y a troublesome, unproductive cough. Water was he mouth, and the resulting cough cleared the ube of a deal of thick mucus, after which the child settled down comfort[illegible] had been in for [illegible] the tube, which within a hour or [illegible] was re-inserted [illegible] chest, cyanosis, and restlessness. The relief was complete and the coughing induced by the tube led to the expectoration of a small piece of membrane. An hour after this the child was again uncomfortable and the breathing was not so satisfactory; water was again given, when she coughed violently and brought up a tough strip of membrane marked with the tracheal rings On the 13th the tube was expressed after it had been in the larynx for 70 hours. The after-expectoration was occasionally streaked with blood and the child was aphonic for seven days. But for subsequent paralysis she made an excellent recovery and was discharged on May 30th.

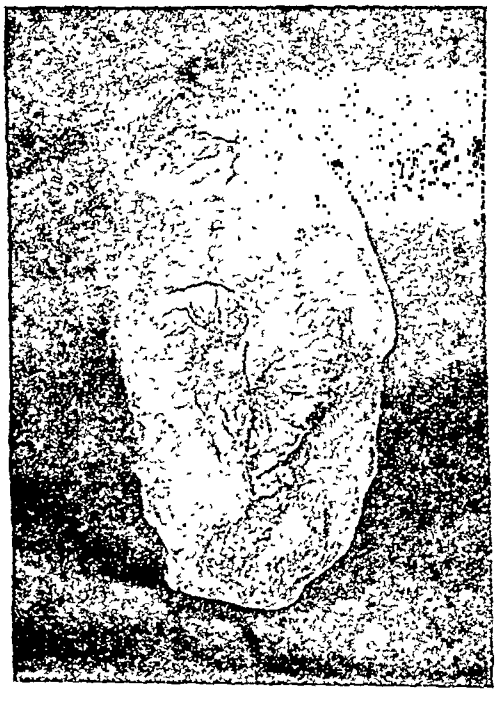
A further point is illustrated in the following case—namely, expression of the tube when necessary by the nurse.

CASE 3 —A boy, aged two and a half years, was admitted to hospital on Jan 31st, 1901, at 3 30 P.M. in urgent distress. A hurried faucial examination revealed thick and firmly adherent membrane on the tonsils. The child rallied somewhat whilst I was preparing to perform tracheotomy, so I intubated the larynx and this gave complete relief. On Feb. 1st, 17 hours after admission, the child suddenly became uncomfortable, with signs of increasing obstruction. Before I could get to the ward "he struggled violently to get his breath" when the nurse instantly expressed the tube, and with it came a hollow cylindrical piece of membrane one and a quarter inches long and marked with the tracheal rings. I found the boy regaining his normal colour and coming round in every way satisfactorily. Within two hours, however, the signs of obstruction returned, necessitating re-intubation, and during the operation the examining finger detached a piece of membrane from the posterior surface of the epiglottis. I was sent for again in the evening of the same day 12 hours after re-intubation; the child had had a fit of coughing, excited by the sips of water ordered, and had brought up another almost complete cylinder of membrane two inches long and nearly half an inch wide On Feb. 4th I expressed the tube; it had been in the larynx for 50 hours, and but for some complications of diphtheria no further anxiety was experienced. The boy was discharged on April 6th the picture of health

For intubating the larynx I always adopt the dorsal decubitus position for the patient. Much valuable time is saved thereby should tracheotomy become necessary, for, indeed, intubation should never be attempted in diphtheria without all the requisites for a cutting operation being close at hand. I will not discuss the method of introducing the tube, but will at once proceed to recount some of the difficulties which I have experienced. Nearly all the patients require the introduction of a gag, and I have seen the breathing during this process become so severely embarrassed, and even cease so that instant tracheotomy was necessary (*vide* Case 4). Great care and gentleness must therefore be exercised in introducing this instrument, it should be inserted on the left side, away from the operator, it being noted that the tongue has fair play and that the mouth is not unduly widened For toothless children the index finger of the assistant inserted as far back as is convenient between the upper and lower jaw is all that is necessary. For patients who refuse to be gagged a very simple plan is to excite the reflex by passing the index finger behind the last molar teeth. I need hardly mention that any struggling should be controlled without in any way embarrassing the movements of the chest and abdomen, an assistant for this purpose standing on the right side of the table behind the operator. Severe swelling of the laryngeal mucosa with an ill-defined epiglottis is not uncommon and may preclude all possibility of intubation; indeed, the propriety of attempting it under these conditions is questionable, as it is naturally so in cases of naso-pharyngeal and faucial swelling, combined with membrane almost occluding the faucial cleft and completely blocking the nares.

The tube may slip into the œsophagus; this is very common and is readily discerned by the absence of relief and the gradual shortening of the silk thread attached to the tube. If the epiglottis is held well forward by the intromittent finger this accident is less likely to happen. Spasm of the glottis (*vide* Case 5) may be so persistent that the tube will not enter for quite an appreciable space of time, whilst the patient's condition begins to give cause for anxiety. It usually yields, however, providing the manipulation is extremely gentle, when the succeeding inspiratory effort the bladder. The vagina was afterwards plugged with strips of gauze and a tube was placed in the suprapubic opening.

The growth, of which the accompanying illustration shows the section, has been preserved in the Museums of the Royal College of Surgeons of England and St. Thomas's Hospital. The specimen from which the illustration is taken is described by Mr. Shattock as follows: "Half of an ovoidal tumour, about two and a quarter inches in chief diameter, which was excised with the urethra which it surrounds; on one aspect it is covered with the smooth mucous membrane of the vagina. The urethra has been rendered very tortuous by the growth, the free or urethral surface of which is highly papillary and is comparable with that presented by a villous carcinoma arising from the bladder. At the highest part of the specimen the internal urethral aperture is shown. Histologically, the growth is a papilliferous columnar-celled carcinoma, the epithelium lining its recesses and processes being of a typical cylindrical form without overlying flat cells."



Villous carcinoma of the urethra. From a photograph, almost natural size. The vesical end shows the opening of the urethra and the projection of the growth. The urethra has not been opened in the full length of the section.

On Sept. 3rd some leakage through the vaginal wound was noticed and on the following day the suprapubic vesical pump was fitted. On the 21st a small orifice through which leakage was taking place was touched with nitric acid and the vagina was packed with gauze. On the 24th the urine was ammoniacal, containing phosphates and pus. On the 25th nitrate of silver was used to touch the edges of the fistula. On Oct. 16th there was no leakage and the vaginal opening had quite healed. The temperature remained normal throughout except for one rise to 100·2° F. the day after the operation. Some days after the operation her mental condition changed and she became wandering in her speech and suspicions in her manner; this abnormal mental state gradually improved and passed away. She left for a convalescent home on Oct. 17th, having been supplied with a suprapubic tube and portable rubber urinal.

The patient attended at the hospital nine months after the operation in response to a letter requesting her to do so. She had put on flesh and had lost the pale, anxious look. The condition of the parts was quite satisfactory and the apparatus worked well. She was wearing, in addition to the usual suprapubic tube, a second tube which fitted into this at a right angle and was of smaller size, the upper open end of which was fixed to the undervest by means of a safety-pin some 12 inches from the junction with the larger tube. This addition was worth making as it improved the action of the apparatus considerably. It was, Mr. Battle believes, first made at the suggestion of Mr. Makins by Messrs. Down. The patient expressed her opinion of the apparatus very strongly: "It's just beautiful, sir."

Remarks by Mr. Battle.—A similar case of carcinoma involving the urethra and bladder in a woman, aged 60 years, was under my care in the year 1894, and an account of it was published in The Lancet of June 15th, 1895, p. 1512. At the operation in that case a similar free removal of the growth was made and the subpubic wound was sutured; in that case, also, a permanent drainage was arranged above the pubes. The result appeared to promise well, but the patient disappeared and has not returned to the hospital since, so that no fresh information can be given of her. The result in this second case as regards comfort and smooth working of the apparatus is very satisfactory. At the time of the first operation I was unable to find any precedent for the course which I followed, but in searching the literature on the subject afterwards a case of removal of extensive growth of the parts with similar treatment of the bladder was found to have been recorded by Dr. J. H. Dunn,[1] U.S.A., when the relief was very striking.

The contrast between these very rare cases of primary malignant growth of the urethra, which hardly excited alarm or discomfort until obstruction was caused by the size of the tumour, and the distress caused by the common urethral caruncle, even when of small size, is very interesting. I have heard of a case of similar character which has been operated on since this one, but it has not yet been published and I have no particulars.

GUEST HOSPITAL, DUDLEY.

A CASE OF INTUSSUSCEPTION WITH SPONTANEOUS REDUCTION; RECOVERY.

(Under the care of Dr. Arthur S. Underhill.)

That spontaneous reduction of an intussusception may occur cannot admit of doubt, but it is probably an exceedingly rare event, at least in cases in which the diagnosis of intussusception has been made. Yet a certain number of cases have been recorded in which patients have exhibited all the signs of intussusception, and when death has occurred a few days later no invagination of bowel has been present, though a portion of the intestine has shown some constriction or congestion.[2] It is likely that in most of these instances of spontaneous reduction the intussusception has affected only the large intestine. For the notes of the case we are indebted to Mr. F. A. Simpson, assistant house-surgeon.

A girl, aged eight months, was admitted into the Guest Hospital, Dudley, on March 25th. She had been sent by a medical man with a history of "some internal trouble." On admission the child was very pallid; she had an anxious expression and cried out as if in pain at frequent intervals; this crying continued for two days. The patient was immediately sent to bed. The mother gave a history of the child passing blood by the rectum and said that she had vomited everything since the day before. On examination the child was found to be very collapsed and almost pulseless. On palpation there was the definite swelling to be felt just external to the outer border of the left rectus which was very rigid. The swelling might well be described as "sausage-shaped." On making a rectal examination a lump could be felt in the rectum about two and a half inches from the anus. The finger could be passed completely round this lump and almost into the mouth of it. There was a blood-stained, slimy discharge from the rectum, but not very profuse. After making his examination Mr. Simpson had little doubt in his own mind that the case was a definite intussusception. He immediately telephoned to the surgeon of the week, Dr. Arthur Underhill, to come to see the child with a view of operative interference. He arrived about 8.30 P.M., a few hours after the child's admission. He made a careful examination and was fully convinced that it was a definite intussusception. On rectal examination the intussusception had come down another half an inch at least and was even more pronounced than before. Dr. Underhill came to the conclusion that the child was too collapsed to stand an operation and consequently treatment was confined to keeping up her strength. No attempt at reduction was made The child was given 30 minims of brandy hourly and milk if it could be retained She slept most of the night, but vomited after all milk given until 6 A M when she retained two drachms, but she retained the brandy given hourly Boiled milk-and-water (half an ounce of each) was given every half hour and 30 minims of brandy were given every hour During March 26th the patient vomited after each feed The blood-stained discharge continued this day and also the next She vomited nine times during the night and after each feed on the 27th She vomited seven times during the night of the 27th On the 28th she began to improve, she did not vomit and the blood-stained slimy discharge from the anus ceased, but the intussusception could still be plainly felt per rectum On the 29th the bowels were well open, the motion being semi-solid and dark brown in colour She did not take nourishment well that day The bowels were opened twice during the night On April 2nd the motions became greenish and contained some slime This condition continued for two days The child improved daily On the 10th she sat up in her cot playing with toys and taking a lively interest in her surroundings She left the hospital on the 17th The child was examined per rectum before she left the hospital and a distinct thickening was felt in the bowel, but the intussusception was completely reduced No slough of the intestines came away at any period.

---

[1] Annals of Surgery, 1894, vol. i., p. 461.

[2] F. Treves: Intestinal Obstruction, 1899, p. 382.

Remarks by Mr. SIMPSON —Cases of intussusception with spontaneous reduction are, I believe, exceedingly rare Ashby and Wright say "Recoveries after spontaneous reduction and after sloughing have been recorded, but they are so rare that waiting for a natural cure means practically abandoning the child to almost certain death" A form of chronic intussusception in children somewhat resembling a prolapse of the rectum is mentioned and chronic invaginations are recorded, Treves reporting one of a year's duration and other doubtful ones; but this case was definitely acute and there is no doubt in my own mind that it underwent spontaneous reduction I have every hope that the patient will have no further trouble I am indebted to Dr. Underhill for his kind permission to report the case

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON

Researches in Tetanus Toxin.—Improved Form of Hæmoglobinometer —Chemical Constitution of the Tubercle Bacillus —Experimental Arthritis produced by the Rheumatic Bacillus —Lantern Demonstration, Exhibition of Specimens, &c

A MEETING of this society was held in the new Pathological Laboratory of the University of Oxford on July 6th, Mr W WATSON CHEYNE, the President, being in the chair

Dr JAMES RITCHIE (Oxford) detailed further experiments bearing on the Relation of Resistance to Tetanus Toxin in the Immunised Guinea-pig to the Antitoxin Value of its Serum The method of immunisation used was to administer at intervals of four days equal doses of tetanus toxin the toxicity of which had been destroyed by means of hydrochloric acid. He had compared the action of four such doses with the action of eight doses In the former case while the animals presented a resistance to 43 minimal lethal doses there was in the whole blood of the animal just sufficient antitoxin to neutralise between one and two minimal lethal doses. In the latter case while a resistance to 1000 minimal lethal doses was present there existed in the serum of the whole body only sufficient antitoxin to neutralise about 100 minimal lethal doses Two other series of animals similarly treated gave similar results In a further experiment, when the effect of four doses of modified toxin was compared with the effect of four doses of double the amount of toxin, a resistance to 2500 minimal lethal doses was developed in the latter, as against a resistance of 50 minimal lethal doses in the former, the antitoxin value of the sera being about the same. The general conclusion was that early in the process of immunisation there was developed a very high degree of resistance while there was very little antitoxin present in the blood.

Professor SIDNEY MARTIN made a preliminary communication on the Inhibition of the Growth of the Typhoid Bacillus in various kinds of earth and under various conditions

Dr J S HALDANE (Oxford) described a modification of Gowers's Hæmoglobinometer Instead of the usual standard of picro-carmine jelly he used a 1 per cent solution of ox blood saturated with carbonic oxide and sealed in coal gas By this means he had obviated the disadvantages of the picrocarmine standard—viz, (1) it did not alter with time, (2) it was always a constant colour, and (3) it could be used in artificial light

Dr W BULLOCH and Dr J J R. MACLEOD communicated some of the results of an investigation into the Chemistry of the Bacillus Tuberculosis The research was undertaken chiefly in order to ascertain to what chemical substance these bacilli owed their peculiar "acid fast" properties In confirmation of the work of Aronson they found that, after thoroughly extracting the bacilli with alcohol ether containing 1 per cent hydrochloric acid the acid-fast properties disappeared from the bacilli The extract on cooling deposited a white scaly precipitate This was separated and was found to stain deeply with carbol fuchsin, retaining the stain even after treatment with 75 per cent. sulphuric acid The extract also contained a lipochrome, a considerable amount of fatty acid, and only a trace of a neutral fat The extracted bacilli were then treated at 60° C with between 2 and 3 per cent. caustic potash till all proteid had been removed. The residue was found to contain about 3 5 per cent nitrogen and to yield on hydrolysis a body capable of reducing cupric salts in alkaline solution They suggested that the sediment might therefore consist, in part at least, of chitin Sufficient material had not yet been prepared in order to decide this question Rüppel and others suggested that the acid-fast properties of the bacilli might be due to chitin, since it has been observed that this substance was very "acid fast" and also that certain fungi contained it Dr Bulloch and Dr Macleod found, however, that chitin did not retain the fuchsin stain when the usual procedure was adopted, but that by leaving the chitin in the stain for 24 hours it was fast, even to 50 per cent. sulphuric acid They found also that the wax-free residue of the bacilli was acid fast after 24 hours' staining

Dr F J POYNTON and Dr ALEXANDER PAINE made a communication on the Arthritis Produced in Rabbits by the Intravenous Injection of the Diplococcus isolated from Cases of Rheumatic Fever They first gave an outline of their researches into the bacteriology of rheumatic fever from January, 1899, to June, 1901 They had isolated a minute diplococcus from 18 cases of rheumatic fever which maintained its virulence for long periods in media of slight acidity and also grew in media of high alkalescence This organism they believed to be identical with that described by Triboulet, Wassermann, and Meyer They had demonstrated it in the tissues of men and had produced by intravenous inoculation the "symptom complex" of rheumatic fever in rabbits The results obtained having been so constant and the number of cases now investigated being sufficient, it was, in their opinion, justifiable to apply the name "diplococcus rheumaticus" to this organism The arthritis that was produced in rabbits (specimens of which were exhibited), though a frequent occurrence, was not invariable It varied in severity and resembled in this respect rheumatic pericarditis in childhood, though, as clearly stated by Wilks and Moxon in their work on pathological anatomy, similar grades of severity were also to be recognised in the rheumatic arthritis of man, though with less frequency The exudations were clear or blood-stained, turbid, or fibrino plastic The sheaths of the tendons round the joints and the bursæ in the neighbourhood were sometimes affected together with the joints The first symptoms usually appeared upon the third day, though sometimes more than a week elapsed It was a polyarthritis especially of the larger joints and it frequently ended in complete recovery. Two cases became chronic and much thickening of the fibrous tissues of the joints resulted. In the acute stage there was gelatinous swelling of the fibrous tissues of the joint and the amount of exudation might be little or much The organisms were rapidly destroyed by leucocytes and endothelial cells, and a section through the joint capsule in the early stage showed much cellular exudation in the delicate areolar layer which bound the endothelial lining of the joint to the fibrous layer The difficulty that was experienced in obtaining cultures from rheumatic synovitis of moderate severity was, they believed, clearly explained by this extensive cellular reaction which brought about a rapid destruction of the diplococci. In conclusion they summarised their observations upon the arthritis produced in rabbits as follows. Arthritis was frequent but not invariable. It was a polyarthritis affecting especially the larger joints. It was of varying severity and sometimes recovery ensued. There might be acute swelling of the fibrous tissues causing a gelatinous appearance or a chronic fibrous thickening of the joint capsule. The exudations were clear, blood-stained, turbid, or fibrino-cellular. The diplococcus was demonstrable in the exudations, but with difficulty in the most acute and in the chronic phases. The diplococci were destroyed by leucocytes and endothelial cells and probably gained access to the joints by the minute blood capillaries in the areolar layer of the joint capsule. Macroscopical and microscopical drawings and specimens were shown illustrating these researches.

Dr. PURVES STEWART gave a lantern demonstration of the Degeneration following a Transverse Lesion of the Cord at the Level of the Sixth Cervical Segment in the Human Subject. The Marchi method was employed. In addition to the ordinary ascending and descending degenerations special attention was directed to the following points. 1. The existence of a new descending tract—"Tract X."—in the cervical region, ventro-external to the crossed pyramidal tract and at a plane corresponding to the tip of the lateral horn. 2. The existence of ascending degeneration in the pyramidal tract *above* the level of the lesion. 3. The presence of degeneration in the anterior commissure of the cord for three segments below a cervical lesion. 4. The probability that the descending degeneration in the posterior columns, extending down to the coccygeal region and constituting successively Schultze's comma tract, Bruce and Muir's septo-marginal tract, Flechsig's oval field, and Gombault and Phillippi's *triangle médian*, was really all one long combined system. 5. The fact that ascending degeneration of the posterior columns did not stop short at the posterior column nuclei, but continued upwards in the arcuate fibres above.

Dr. N. BISHOP HARMAN exhibited a series of Water-Colour Drawings, Microscopical Specimens, and Cultures of the Veldt and Natal Sores. The veldt sore was, he said, a vesicle or blister forming in the stratum lucidum of the epidermis. Cultures from the serous discharge yielded a diplococcus growing freely on ordinary media and resembling staphylococcus aureus in some respects. In aerobic cultures it grew as a diplococcus. It exhibited a most extraordinary resistance to the usual destructive agents. It would grow in a moist heat of 86°C., in a dry heat of 110° C., and it had retained all its virulence in a dry film for 61 days. He had soaked cultures of the organism in equal parts of 1 in 1000 perchloride, and yet they would grow afterwards. The veldt sore was only found in the dry, rather barren, high tableland of South Africa. It affected the troops to the extent of over 20 per cent., mounted men being attacked in almost twice the proportion to infantry. It affected the Boers also, but not to such an extent as it did the British. The Natal sore was found in the lower parts of Natal where vegetable life and animal life were abundant. It was essentially an abscess of the true skin, and yielded the staphylococcus pyogenes aureus both on film and culture preparations.

Dr. A. WATERS showed a number of Microscopical Sections of the Rarer Tumours. Of these the most interesting was a secondary malignant growth invading a dermoid cyst, giving rise to metastasis in various organs. The tumour conformed to no regular type but much resembled "deciduoma malignum" histologically.

Dr. H. L. BARNARD exhibited the organs taken from a boy, aged nine years, who had died from the effects of an accident. The patient had been the subject of a calcified aneurysm of the renal artery, and this by the force of a blow on the back had been driven into the liver, causing rupture of that organ.

OBSTETRICAL SOCIETY OF LONDON.

Spontaneous Rupture of the Uterus in Placenta Prævia.—Exhibition of Specimens.

A MEETING of this society was held at 20, Hanover-square, W., on July 3rd, Dr. PETER HORROCKS, the President, being in the chair.

Dr. J. PRESTON MAXWELL (Amoy, China) read a paper on Spontaneous Rupture of the Uterus in Placenta Prævia. He had met with three cases of this accident. In the first case the woman died undelivered within a few minutes of the rupture; in the second case, the uterus was found ruptured posteriorly after delivery and the patient had dangerous hæmorrhage, but recovered after packing of the rent by antiseptic gauze. The details of the third case were as follows. The patient, a primipara, aged 23 years, had been in poor health during her pregnancy. Fortunately she was more enlightened than were the majority of Chinese women, and she called Dr. Maxwell in when labour began. She had weak, poor pains, and the child was evidently at full term; the cervix dilated very poorly, especially posteriorly. There was a little more bleeding than usual, and this combined with the irregular dilatation of the os, which would admit two fingers, caused a suspicion of placenta prævia, and the edge of the placenta was felt behind. As she lived close by it was decided to get her into a better condition by procuring some sleep, and to that end she was given a dose of chloral and bromide. She went to sleep, and when next visited, about 12 hours after, the cervix had closed up and it admitted one finger with difficulty. There was no further hæmorrhage, and at the end of 14 days labour came on and the os dilated, but still it did not dilate well behind. When it was nearly dilated Dr. Maxwell left the room for some two or three minutes, but returning found that the patient was beginning to bleed badly, and he at once ruptured the membranes, and, the child's head coming down, he placed his hand on the uterus and kept it there but without in any way stimulating it. At the end of 10 minutes the child was born without assistance. The moment the child was out of the vagina blood simply pumped out and death appeared imminent. Turning the patient on to her back he quickly expressed the placenta and, with his hand on the abdomen, pressed the uterus forcibly downwards and backwards and administered ergot by the mouth and by hypodermic injection. The bleeding, which had been checked by the pressure of the uterus downwards, came from a rent of the posterior wall of the uterus and the cervix and the examining finger could be passed directly into Douglas's pouch. He packed the rent with gauze wrung out of biniodide of mercury lotion and kept up pressure on the uterus for two hours. The gauze was removed in 24 hours. No douche was given and no septic symptom arose and her recovery was uneventful. The child weighed five pounds and was puny. At the end of three weeks the child developed pneumonia owing to a chill and died after two days' illness. The placenta was a placenta prævia marginata and the rupture had occurred through the entire cervix and lower portion of the placental site. It was well known that in cases of placenta prævia the wall of the uterus was not strong and in some cases fatty degeneration of the uterine muscle had been discovered. What exactly sets up the rupture in these cases it is difficult to tell. A severe pain accompanied by an expulsive effort is sufficient to start the rent, and once started it is apt to enlarge mechanically. As to the treatment, laparotomy and suture would have been extremely difficult and almost certainly fatal. And it was impossible to suture the rent per vaginam, especially in a dirty Chinese home.

Dr. F. H. CHAMPNEYS said that the case was remarkable in several ways. The small size of the child, the absence of malpresentation, the absence of interference, and the absence of anything in the history to account for the accident combined to make it worthy of record. As to the treatment which had been adopted he thought that it was perfectly correct; the plugging of the rent with gauze was the most successful treatment in cases in which the fœtus and placenta had not escaped into the peritoneal cavity. He was not, however, surprised that the case was well treated, as Dr. Maxwell (who had only lately been his hospital assistant) was well known to him.

Dr. G. E. HERMAN concurred with what Dr. Champneys had said as to the merit of the paper. Dr. Maxwell had quoted some current statements without, however, indorsing them as his own, and therefore he could hardly be held responsible for them. He said that in placenta prævia the uterus had been observed to be soft. It was true that some writers had said so; others had said that it was hard. He (Dr. Herman) did not think that there was any marked or constant difference in consistence between the uterus with placenta prævia and any other pregnant uterus. Dr. Maxwell had also said that spontaneous rupture of the uterus was due to fatty degeneration, and in that he followed the statements of eminent writers on midwifery. But he (Dr. Herman) knew of no good evidence to show that fatty degeneration of the uterus was present in cases of rupture of the uterus.

Fatty degeneration of the uterus had been said to take place in the puerperium, but the more recent researches of Helme showed that it was no part of the process

Dr Drummond Robinson, in reference to points raised by Dr Herman regarding fatty changes in the involuting uterus, stated that he had had the opportunity of examining microscopically two specimens of involuting human uterus Careful staining with osmic acid failed in both instances to demonstrate the presence of fat.

Dr Herbert Spencer said that the case was one of unusual interest and had been judiciously treated and well recorded He was pleased to find that in two cases mentioned by Dr Maxwell in which gauze-packing had been employed recovery ensued. Dr Spencer had called attention to this method of treatment in a paper read before the society last year, giving notes of four cases successfully treated in this way His previous experience had been that in every case of rupture of the uterus (about eight in all) the patient had died At the present time it was usual to recommend abdominal section for complete rupture of the uterus, but that operation, especially if followed by hysterectomy, was generally too severe a shock for a patient suffering from a rupture of the uterus, and if those with experience of that accident would publish all their cases as he had done he had no doubt that the results of hysterectomy would compare very favourably with those given of gauze-packing

Dr Amand Routh had seen one case of spontaneous rupture of the uterus with placenta prævia The patient was eight months pregnant and had had several attacks of hæmorrhage. Under deep anæsthesia the cervix was found to be rigid and it was not easy to insert the finger An anterior marginal placentation was found The tongue of placenta was separated from the lower uterine segment, podalic version was performed, and the leg was brought down to the half-breech, which was left *in situ* for nature to complete the delivery In about 24 hours, the patient's medical attendant being then in charge, labour pains came on and the child and the after birth were spontaneously expelled In two days septicæmia was evident and the practitioner in attendance then found that the uterus had ruptured anteriorly In spite of all treatment the patient died He had no doubt that Dr Maxwell's treatment by packing the rent with antiseptic gauze was the correct one to adopt, arresting hæmorrhage and securing drainage

The President thought that the treatment was not only excellent "in a dirty Chinese home" but was the very best treatment in a London or any other hospital with every appliance available The treatment of rupture of the uterus by packing with gauze was most successful in saving life He certainly considered that much of this success was due to the fact that the parts had not been rendered septic by the accoucheur's hands He related details of a most extensive rupture of the uterus which was treated by packing, this being renewed under chloroform every day for 12 days in succession and then less frequently The patient then became very ill and at last a large slough was extracted from the right broad ligament, and ultimately the patient recovered

The following specimens were exhibited —

Dr Cuthbert Lockyer A Menstrual Membrane from a case of Exfoliative Endometritis

Dr Richard Alcock Microscopical Sections of a Cyst of a Corpus Luteum

Dr J S Fairbairn (1) A Primary Carcinoma of the Ovary, and (2) an Incomplete Tubal Abortion

Mr A C Butler Smythe (1) A Cancerous Uterus removed 18 years after Double Ovariotomy, and (2) a Diverging Traction Forceps for Vaginal Hysterectomy

Dr William Duncan Two Fibro-myomatous Uteri (one Cystic) removed by [illegible]

The specimens [illegible] Dr W F V Bonne[illegible] A Doran, Dr Dunca[illegible] iles, Dr Herman, Dr Drummond Robinson, Dr Amand Routh, *Dr Herbert Spencer*, and Dr W W H Tate.

OPHTHALMOLOGICAL SOCIETY

Blindness resulting from Sodium Salicylate —Melanotic Sarcoma of the Conjunctiva (sequel) —Conjunctival Bridges and Pouches due to Union of Retrotarsal Folds —Sympathetic Irido cyclitis (recovery) —Exhibition of Specimens

The last ordinary meeting of the session was held on July 5th, Mr G Anderson Critchett, the President, being in the chair

Mr Simeon Snell related the following case of Blindness resulting from Sodium Salicylate. The patient, a girl, suffered from acute articular rheumatism, for which sodium salicylate was prescribed She woke from sleep at 7 30 A M and said that everything was dark in front of her On the medical attendant's visit between 11 and 12 he found her unable to distinguish between light and dark The next day Mr Snell saw her and found her perfectly blind The ophthalmoscope disclosed nothing abnormal in either fundus The following day he again saw her, when she was succumbing to pericarditis with endocarditis Again nothing abnormal in either fundus was detected There was no return of vision and she died that same evening It was calculated that the total quantity of sodium salicylate taken must have been 140 grains, if not 160 grains, in 60 hours Mr Snell said he thought that there could be very little question that the sodium salicylate was the cause of blindness in this instance The number of similar cases recorded was very limited

Mr J B Lawford reported further notes of a case of Melanotic Sarcoma of the Conjunctiva The patient was a woman whose conjunctiva showed marked and increasing pigmentation when she was shown to this society on June 11th, 1896 In July 1896 two pinkish nodules appeared In August, 1896 the cornea became hazy and the intraocular tension raised In October, 1896, the eyeball and conjunctiva were removed and were examined by Mr Devereux Marshall who reported the growth to be a pigmented sarcoma The pinkish nodules consisted of connective tissue cells, and blood vessels There was no growth whatever within the eyeball In May, 1897, the patient had a serious illness with brain symptoms, and it was thought that an intracranial growth was present. However she got better In October, 1897, some new growth was seen in the orbit and the general health was not good On Oct 21st, 1897 the growth was removed and was examined and found to be a sarcoma In August, 1898, another recurrence was seen On Sept. 1st, 1898 the growth was removed and examined by Dr Jenner and found to be a sarcoma. In April 1899, another pigmented spot was seen, and in the following September another had appeared in the upper lid On Sept 14th, 1899, the whole contents of the orbit were removed On March 20th, 1900, the patient was very ill and died on April 28th, but no necropsy was obtained. Mr Lawford unfortunately did not hear of her death until some weeks later Owing to the patient's very irregular attendance and also to her refusing operation in the early stage of the disease her chances of cure were much diminished

Major H Herbert, I M S (Bombay), described Conjunctival Bridges and Pouches due to Union of Retrotarsal Folds, a condition found in nine upper lids of seven patients of all ages One or more retrotarsal folds had contracted permanent adhesions with the tarsal conjunctiva evidently while displaced downwards through swelling in some previous inflammatory attack The adhesions were sometimes multiple along the summit of the one fold, in other cases smaller adhesions of underlying folds were found beneath the principal ones The folds had retracted, except when held by the adhesions thus leaving the permanently displaced portions as broad or narrow bands, or bridges of conjunctiva connecting tarsus and fornix and freely admitting the passage of a probe beneath them There was no history of injury in any case, but in the majority there was or had been trachoma Two cases were also mentioned in which small bridges of union had formed between folds in the lower fornix In another patient recovering from acute conjunctivitis (membranous or pseudo membranous) the actual formation of these adhesions was seen. The union was primarily by means of fibrinous exudation which apparently became organised Finally, another upper lid was mentioned in which a broad fold came down over the tarsus and had adhesions not only at its summit but also over the greater part of its surface, leaving only a shallow pouch or pocket under each curved lateral margin —Dr Bishop Harman stated that he had seen a similar condition in a patient in South Africa who had previously suffered much from grit in the eye

Mr Sydney Stephenson communicated notes of a case of Mild Sympathetic Irido cyclitis in a child 54 days after removal of an injured eye The interval between the original injury and the enucleation of the eye was 20 days The injured eye was affected with puro-plastic cyclitis, but micro-organisms could not be recognised. The patient when seen 16½ months after the accident had made a complete recovery.—The PRESIDENT referred to an observation of Liebricht that pressure on the nerve stump in the vacant orbit was painful in these cases.—Mr. DEVEREUX MARSHALL asked Mr. Stephenson if this was a record case. He himself had seen a mild case develop between two and three weeks after an eye had been removed for injury, but he had never seen a case develop so long as 54 days after enucleation.—Mr. SIMEON SNELL narrated a case of recovery of both eyes under similar circumstances. Enucleation sometimes sacrificed the better eye of the two.—Mr. STEPHENSON said that he was not certain what was the longest interval observed, but he did not think that his was the longest on record.

The following cases and card specimens were shown:—

Mr. C. WRAY: Gumma of the Orbit which occurred 40 years after Primary Syphilitic Infection.

Dr. W. C. ROCKLIFFE: Cystic Growth of the Retina (probably Carcinoma) Secondary to a Primary Scirrhus of the Breast. There was evidence of both eyes being affected.

Mr. MARCUS GUNN: Exceptional Appearance of a Choroidal Lesion, probably tuberculous.

Mr. INGLIS TAYLOR: Peculiar Form of Vitreous Opacity.

Dr. HARMAN: Hole in the Macula.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

Alcohol in its Medical and Scientific Aspects.

THE tenth ordinary meeting of this society was held on July 3rd, Dr. A. G. MILLER, the President, being in the chair. The meeting was devoted to a discussion on Alcohol in its Medical and Scientific Aspects.

Professor G. SIMS WOODHEAD, in opening the discussion, said that it was always well to have clear issues and that before they could discuss the matter reasonably they must arrive at some agreement as to what category alcohol must come under. Was it a poison, a drug, or a food? Or if it were all three, as some maintained, in which did it play the most important rôle. As a food, or even as a drug, did it play a part anything like so prominent as it did as a poison? All agreed in believing that alcohol was a narcotic poison, and certainly as a pathogenetic agent it was a protoplasmic poison. Certainly alcohol was a drug, but it was not a panacea for all ills. Let them keep alcohol as a drug and use it and prescribe it as any other drug, not loosely, but with a definite end in view, and at any rate with some show of scientific precision. The third question, Was alcohol a food? interested them greatly. It was this view of it which rendered it responsible for the greater part of the diseases which were now ascribed to its action. Few physiologists denied that alcohol was oxidised in the body, and to that extent might supply a certain amount of heat, but that any sane man would put forward alcohol as able to supply the number of calories required by the body and easily given by carbohydrates and fat was scarcely conceivable. Quite recently Dr. John Madden, criticising Professor Attwater's teaching on the food value of alcohol, pointed out that it differed from fats and carbohydrates in so far that it was a violent protoplasmic poison whilst they exerted absolutely no toxic effect. Ehrlich's views were important, and he stated that the nutrition of cell protoplasm appeared to result from a combination of certain proteid elements with the cells. Certain bonds or links were necessary for the application of nutritive substances to the use and nutrition of the cell. All these links appeared to be connected with the nitrogenous element. Now alcohol did not contain this nitrogenous element. It entered into combination with the protoplasm but apparently in quite a different fashion from the nutrient substances ordinarily utilised by the cell and acting rather as a toxic than as a nutrient substance. Dr. Madden pointed out that there was absolutely no evidence to show that alcohol might act as a respiratory food or that it was converted into a reserve supply of fat, but that instead of protecting nitrogenous tissues from undue waste (as did the fats and carbohydrates), alcohol actually hastened their waste, acting as a protoplasmic poison. Another important feature in connexion with alcohol as a food was the extraordinary avidity that it, like phosphorus, appeared to have for oxygen. This was probably one of the prime factors in producing certain forms of fatty degeneration. Under ordinary circumstances fat and carbohydrates taken into the body were readily oxidised by the respiratory oxygen. With alcohol, however, they had a much more active process. It became oxidised under conditions in which oxidation of fat and carbohydrates could not take place, and, like phosphorus, it appeared to divert to its own use oxygen which normally would go to protect nitrogenous tissues from undue waste, thus leading to derangement of their functions and metabolism. It interfered with the normal oxidation of carbohydrates and fat and to that extent set up abnormal metabolic processes which ended in the destruction of protoplasm and in the accumulation of the resulting fatty degenerative products in the protoplasm. This change was seen best in the heart muscle, but took place in muscular tissue throughout the body generally. In these secondary fibrous and calcareous changes occurred, thus leading to premature senility and thus directly due to alcohol. Like phosphorus or the products of micro-organisms and alcohol, they offered them evidence of the danger of assuming that because it was readily oxidised in the tissues alcohol was to be looked upon as a substance useful in the animal economy. In the case of alcohol they appeared to have this degenerative action on the cells without any accompanying nutrient action. It was because of this want of the nutrient element that the protoplasmic cells did not in time become accustomed to the poisonous action of alcohol as they did to the poisonous action of the proteid toxins. As a result of tissue reaction between the toxin and the cell the tissues of the body as a whole might in time become capable of withstanding enormous doses of certain proteid toxins. In the case of alcohol the process of immunisation was only slightly (then only apparently) increased, the degenerative changes affording evidence that the tissues, at any rate, did not become immune to its action. Professor Woodhead referred to the combined actions of alcohol and arsenic, the tissues "weakened" by one poison being more readily affected by the other. It was also recognised that alcohol in some ways acted as a predisposing cause to specific infective disease. McLeod of Shanghai insisted most strongly on this point. Abbot had shown that the normal resistance of rabbits to infection by the streptococcus pyogenes erysipelatis was markedly diminished by the use of alcohol when given daily to the stage of acute intoxication and indicated that this agreed in a way with clinical observations on human beings addicted to excessive use of alcohol when infected by this organism. Delearde found that animals treated with considerable doses of alcohol were less resistant to the action of the anthrax bacillus, tetanus toxin, and rabies poison, and also that it was a more difficult matter to render and maintain such animals immune to the action of these poisons than it was in the case of ordinary non-alcoholised animals. It was, however, to be noted that all these animals were treated with very large doses of alcohol. Laitenen tried the effect of small doses of alcohol for a lengthened time on animals, and his first conclusions were that alcohol, however given, induced in the animal body a markedly increased susceptibility to artificial infection or poisoning by certain infective and toxic agents, and he stated that the use of alcohol in the treatment of anthrax, tuberculosis, and diphtheria, at any rate, was not only useless but was probably actually deleterious. He stated, as also did Abbot, Welsh, and others, that the predisposing action of alcohol must be looked for in the production of abnormal conditions and pathological changes in the various organs—alimentary canal, liver, kidneys, heart, &c. Alcohol slightly diminished the alkalinity of the blood and favoured some leucopenia during which there seemed to be a slight decrease in the bactericidal power of the blood and an increased susceptibility of the tissues to the action of infective agents. Leitenen pointed out that experiments proved that pregnant animals and their offspring were markedly affected by the continued use of small doses of alcohol. The normal temperature and that in disease were often temporarily but slightly reduced by alcohol and this was the most favourable moment for the invasion of infective agents. As regards the relation of alcohol to phthisis there was direct evidence to show that even in small doses alcohol predisposed to this disease, and this was equally true as regarded the secondary and continued infection. If alcohol increased the susceptibility of the tissues to this infection or interfered with the production of immunity it could scarcely be good as a permanent food substance in this disease. Alcohol insisted on being oxidised in the body and where there was such marked interference with the respiratory processes this might be a most serious factor in bringing about an accumulation of fat in the liver and in setting up a fatty degeneration in the cell of this and of other organs. Mitchell Bruce was satisfied that dilatations of the heart and alterations in the myocardium were of frequent occurrence as the direct result of alcoholism. Professor Woodhead had seen two cases both in young and otherwise healthy people who had died from acute alcoholism in which there was an acute myocarditis without any endocarditis or pericarditis. The heart, however, appeared to be affected by alcohol long before any organic change could be made out in its tissues. Leonard Hill told them that alcohol rendered systolic output incomplete and increased the diastolic pressure and the dilatation of the heart. As regards the influence of acute alcohol poisoning on nerve cells, it had been shown that Nissl's granules gradually disappeared and the protoplasmic basis became slightly stained in the nerve-cells of the cerebral cortex, in Purkinje's cells and in the multipolar cells of the spinal cord, indicating a marked toxic condition such as was met with in connexion with diphtheria, tetanus, and other poisons. The changes were more marked as the dose of alcohol was increased or allowed to act for a longer period. Professor Woodhead described the changes which resulted in the nerve-cells in alcoholic brains. Such lesions of the neuron were not peculiar to the effect of alcohol, but might be reproduced by any irritant drug or bacterial toxic product. They had thus materials on which to found a study of the pathological changes set up by alcohol. Now that the conditions which produced these changes were understood and could to a certain extent be controlled they were more satisfactorily placed for studying the direct changes which took place in these and other tissues and might soon obtain more definite information on many controversial points.

Professor T. R. FRASER said that there were those who thought that alcohol was of the highest value, while there were others who thought that it had no value whatever. It must be admitted that alcohol was a toxic agent, yet it had actions which might be of service in many directions—e.g., to patients suffering from certain diseases and even in certain circumstances to society at large. Enough care had not been taken to discriminate between the effects produced by small doses as contrasted with the effects of large doses. The effects were entirely different. In small doses alcohol stimulated the heart, while in large doses it paralysed it. It was a substance which either improved or destroyed digestive processes and because of the ease with which it was burnt up in the body might give energy and so be of use in certain crises. In considering its actions Professor Fraser noted: 1. Effects on circulation.—There was no doubt but that alcohol acted directly on the heart in small doses so as to increase the force of its contractions and to quicken its action. This rapid stimulating action of alcohol was of value to the circulation as contrasted with the majority of other drugs. Alcohol was readily absorbed and so its effects were speedily produced. There was no subsequent depression following on this cardiac stimulation. The heart merely returned to its normal and was not enfeebled. It had a direct action on the blood-vessels as a result of which they dilated. As a result of this increase in cardiac action, together with the vascular dilatation, there was a widely distributed acceleration in the blood-supply and a consequent stimulation of distant tissues and cells of the body when these might be perishing for want of nourishment. 2. Effects on digestion.—It had been absolutely proved that alcohol stimulated salivary secretion without deteriorating its power. It also increased the peptonising power of the gastric secretion as well as increasing the peristaltic movement of the stomach. This caused, therefore, a more thorough digestion of food. It also induced a [illegible] questions they must deal only with such doses as were proper. Alcoholism was a very satisfactory agent in stimulating primary digestion. It was a tonic to digestion, but only when the dose was moderate. 3. As regards nutrition, alcohol was very easily oxidised. After taking alcohol the output of CO_2 and the intake of oxygen were enhanced. Only an insignificant amount of alcohol was to be discovered in any of the excretions. Such facts showed that alcohol was absolutely burned up in the body and it must therefore generate energy and force and must therefore be a good substance. It was much more readily consumed than either carbohydrates or fats. Professor Fraser did not place it high as a food substance. Its only value lay in allowing them to tide over an emergency, as where a patient was unable to retain any food in the stomach and where death threatened. By giving alcohol in suitable cases they could ward off this and so overcome crises. They could cure such cases by giving alcohol, as it proved not only a food but also acted by stimulating the circulation. 4. Its action on the temperature.—Even in normal conditions as well as in pyrexia alcohol reduced the temperature. This was due to radiation of heat from the body and not from any inhibition of heat production. Alcohol therefore proved very satisfactory in reducing pyrexic conditions. 5. Action on the nervous system.—As physicians they had not much to do with this aspect of the question. The actions of alcohol which were made use of were scarcely those which affected the nervous system at all. The chronic action of alcohol on the nervous system was something totally different, however. 6. As regards the action of alcohol in infection Professor Fraser said that the incidence of plague amongst an absolutely teetotal population gave a case mortality of 95 per cent. in Calcutta, whilst amongst the Europeans who drank alcohol it was only 20 per cent. The same results were seen in the recent outbreak of this disease in Glasgow.

Dr. T. S. CLOUSTON said that alcohol was the greatest factor in producing disease in the higher nerve centres, accounting for from 20 to 25 per cent. of the cases of mental disease. In explaining this, however, one must consider the neuropathic brain, which was really the original predisposing cause of the mental disease. Even if alcohol did not act on these cases many other causes would come into play and act on such brains. In Dorsetshire, for example, there was a good deal of quiet beer-drinking but little ardent spirit was consumed; alcohol was said only to cause 5 per cent. of the cases of mental disease, yet Dorsetshire furnished as many lunatics as were found in Edinburgh. Again, amongst the Society of Friends mental disease occurred to as large an extent as amongst the general population and yet the habits of the Friends were above suspicion. This showed that alcohol as being *the* factor must be conditioned in many ways. In those in whom the brain was easily excited to desire and where inhibition was easily decreased (and this formed a large class, artists, poets, &c.) alcohol produced to an intense degree pleasurable excitement and yet it was one of the most powerful toxic substances. One must put against the increased liability to infectious troubles induced by alcohol the advantages which it produced on the social side. Experiment showed that alcohol led to a liberation of energy. Its first effect was a katabolic one on the higher nerve centres. Then these easily discharged themselves. The effect of a small amount of alcohol was to give slight conscious pleasure and the mental output was increased, but the latter was of a poor sort. Ferrier long ago showed that repeated stimulation of the motor cortex soon led to the production of convulsions. The same happened with alcohol; repeated doses had a much greater effect, as perhaps half the former dose would interfere with mental processes. This effect on the higher centres should be remembered. Some change of a molecular kind took place in these centres and this effect was of a lasting kind. Dr. Clouston thought that much valuable information might be obtained by the appointment of a scientific committee to investigate this. In the treatment of admitted alcoholics one of the great hindrances was that the patient could not help in his own treatment. He needed legislative help, and surely if the whole profession demanded this the legislature would grant it. Taking a broad view of the social customs and the neuropathic brain there was undoubtedly an excessive use of alcohol. If they could by an emphatic expression state that the excessive use of alcohol was very harmful, and if they could make people believe in this pronouncement, they would do a great deal of good.

Dr. J. O. AFFLECK said that the various views had to be brought to the test of experience. His own view in regard to the administration of alcohol was that while he would not like to be without it, yet it was an emergency remedy. He thought that the statements of Professor Fraser were very strong and very dogmatic and open to serious question. One often saw a case of pneumonia in a drunkard end fatally in a short time and this result was simply due to the unfavourable condition of his body induced by alcohol, yet alcohol was much used in pneumonia and given in large doses. Dr. Affleck had been greatly disappointed in such cases in its use. He had rarely seen large doses do any good. He thought that the use of alcohol as an aid to digestion was fraught with terrible danger. If this stimulus to digestion were called into play every day, would it not shortly fail as such, and might it not cause such tissue disintegration that evil results would follow in later life? He felt more and more chary of ordering alcohol and a greater responsibility in doing so. One could not dissociate the moral from the medicinal aspects of the question.

Dr. **JAMES RITCHIE** quoted statistics from life assurance offices to show that the lives of total abstainers were very much better than those of moderate drinkers and said that the 20*s.* per cent. of added premium did not suffice even in those who were merely connected with alcohol in a business capacity. In one office the deaths of total abstainers fell to 23 per cent below the normal expectation of deaths, while in another it fell to 26 per cent. In the industrial insurance companies the same was seen—e.g., the Rechabites were tectotalers while the Foresters were not, and in the latter there were three and a half times as much sickness as in the former. In accident companies total abstainers paid 10 per cent. less premium. In disease, Dr. Ritchie stated that in gout alcohol so modified the vital processes as to predispose to gout and that he found gouty people were much better without alcohol. The same he found with rheumatism. In dilatation of the heart he never gave alcohol. He differed from what Professor Fraser had said regarding the cardiac failure. After giving alcohol they got a failing of the heart after about two hours and so another dose had to be given.

Dr. **J. FOULIS** thought that alcohol had very little effect in sustaining the heart in chronic disease.

Dr. **LESLIE MACKENZIE** spoke regarding the effect of alcohol on infection. Infectious diseases were chiefly confined to the early years of life and at that time alcohol was out of reckoning. At later periods of life alcoholic and non-alcoholic were equally liable to infection. The prognosis in each of these varieties might be influenced but not the susceptibility to the disease. Cholera did not prevail in the western areas where alcohol was used.

Dr. **H. M. CHURCH** spoke regarding the use of alcohol in children. Frequently the physician did not know when to give or when to withhold alcohol in certain ailments of children. His plan was to give small doses and watch the results with the finger on the pulse.

After Dr. **P. A. YOUNG** and Dr. **D. A. WELSH** had spoken,

Dr. **CLAUD KER** said that in diphtheria he used alcohol as a routine and he had noted that when alcohol was not employed in such cases heart failure more frequently occurred. He asked if they were not to give alcohol or strychnine what were they to give in such cases?

Professor **FRASER**, in reply, said that there was a crowd of other cases besides infectious ones where alcohol was of the greatest use. Alcohol required no previous digestion and was absorbed at once, and also exerted its influence immediately. Strychnine, digitalis, and strophanthus acted slowly, and in all probability the patient would be dead before they began to act. His contention was that alcohol was a beneficial medicinal agent.

Professor **SIMS WOODHEAD** said that the strong point in the evening's argument was the admission of Professor Fraser that alcohol should be taken in medicinal doses and only for a brief period. He himself believed that alcohol should be used as a drug, and if alcohol was the only drug necessary then it must be used so as to get a definite result. When small amounts of alcohol were given there was a diminution in the number of leucocytes. Even in minute doses alcohol increased the susceptibility of the animal to infection. There was a rapid increase of energy after taking alcohol, but it was of the nature of an explosion and not of a useful nature. The antipyretic effect was often neutralised by the cumulative action of the poison of alcohol. As regards plague, Europeans were so differently situated and nourished that this might well be the explanation of the lowered case-mortality. By starving animals they could increase their susceptibility to infectious diseases. The taking of alcohol led to the easy production of rhythmical movements—they become automata. When alcohol was given in diphtheria, except in minimal doses, it greatly increased the liability to antitoxin rash.

DIPHTHERIA AT SHIREHAMPTON.—At the meeting of the Barton Regis (Bristol) Board of Guardians held on July 5th it was stated that 79 cases of diphtheria had occurred during the recent outbreak at Shirehampton and Avonmouth, and that there had been no fresh case since June 14th.

Reviews and Notices of Books.

Studies in Human and Comparative Pathology. By WOODS HUTCHINSON, A.M., M.D., Professor of Comparative Pathology and Embryology in the University of Buffalo. Edited by Dr. EDWARD LAKE. London: Henry J. Glaisher. 1901. Pp. 350. Price 12*s.* 6*d.*

RARELY have we perused a medical work with more pleasure that the one now before us. Not only is the matter contained therein most interesting and instructive, but the charming manner in which it is written is irresistible and rivets the attention of the reader. The study of comparative pathology, a science which owes so much to Mr. J. Bland-Sutton, is as yet scarcely past its infancy and consequently the records collected by those who have made it a special study are very valuable. The field which has to be covered is enormously wide, embracing at least the three distinct and usually separated provinces of morphology, veterinary medicine, and human pathology. Dr. Hutchinson has made excellent use of the opportunities afforded him whilst in this country by study at the Gardens of the Zoological Society of London.

The first chapter is headed "The Cell Republic and the Individuality of the Cell in Health and in Disease." A delightful account is given of the "solidarity and the *esprit de corps* that exist between all the body cells," or, more prosaically expressed, of the functions of the red and white blood corpuscles. In the second chapter the Diseases of the Alimentary Canal are considered. Dr. Hutchinson has seemingly an admiration for the simple stomach of the amœba; he describes it as "an impromptu, and can be improvised at a moment's notice on any part of the amœba's surface ...... absolutely simple as the device is, it has its advantages; if one part of the surface become 'dyspeptic,' a new one can be utilised." After careful consideration of such a convenient digestive apparatus he suggests: "Our boasted superiority to our ancestors sometimes brings penalties with it."

"Appendicitis" obviously claims attention in such a work as this and a most interesting account is given of the natural history of the vermiform appendix. The conclusion is arrived at that we have in the human appendix a structure which is not only ancestrally degenerate—intermediate, as it were, between the voluminous and well-nourished cæcum of our more herbivorous ancestors—but is also actually undergoing further atrophy during the lifetime of the individual both before and after birth, and we should expect, therefore, upon morphological grounds to find it a point of least resistance in the food-tube and a frequent starting-point of inflammatory disturbances of every description, and such, of course, is its well-known surgical and medical history. As Dr. Hutchinson remarks there is no need to call in the aid of foreign bodies or concretions of any sort, fæcal or otherwise. Very interesting also is the chapter on the Lungs, their Morphology and Pathology. The peculiar vulnerability of the lungs to disease is discussed at length, and the author points out a distinctive and unvarying characteristic of the lung, as an organ, which marks it off from almost all other organs of the body as abruptly and as positively as does its marked liability to the attack of disease, and that is its extreme recentness. With the exception of the uterus and mammary glands there is no organ of the body which has not from five to 10 times the length of ancestral history that the lung has It is argued, and we think justly, that the longer a given organ has performed its functions in an adequate and satisfactory manner the more likely it will be to continue to perform that function, undisturbed by any influences which may be brought to bear upon it. We would willingly quote Dr. Hutchinson's own language further, but we have not space. His suggestions as to the predisposition of the lungs to tuberculous disease are lucid and powerful and afford most interesting reading.

The chapters on Tumours and Tuberculosis contain a vast amount of information and demonstrate the powers of observation and description possessed by the author. We can cordially recommend this volume and heartily congratulate Dr. Hutchinson on the result of his labours.

Purulent Nasal Discharges: their Diagnosis and Treatment. By HERBERT TILLEY, B.S., M.D. Lond., F.R.C.S. Eng., Surgeon to the Throat Hospital, Golden-square; Lecturer on Diseases of the Nose and Throat, London Post-Graduate College and Polyclinic. London: H. K. Lewis. 1901. Pp. 120. Price 4*s.*

DR. TILLEY says that no apology is necessary for the publication of a treatise on a special subject of such general importance as nasal suppuration, and with that we cordially agree. To the practitioner of general medicine in particular the subject is of the utmost importance, for, as Dr. Tilley points out, it is often that general malaise, if not a much more serious disturbance of the digestive functions, is due to the frequent ingestion of septic matter from the nose. In chronic empyema of the antrum, for example, the relief that is immediately given through correct diagnosis and treatment is almost magical, and the intelligent perusal of a work by such a careful observer as Dr Tilley will do a considerable amount towards rendering the practitioner capable of giving *this relief.*

The subject-matter is classified under the following six headings: purulent nasal discharges met with in early infancy, discharges associated with the exanthemata and other acute infectious disorders, nasal manifestations of constitutional disease in the adult, pathological conditions of the nasal or post-nasal mucous membranes, foreign bodies in the nasal cavity, and disease of the trans-nasal accessory cavities.

In nasal syphilis Dr. Tilley advocates the practice of mercurial inunction, a line of treatment that receives wide support; but he does not allude to mercurial fumigation, a method that has given excellent results and one which, in view of the later ideas on the mode of action of mercury when used as inunctions, would suggest itself as being of considerable value in nasal syphilis. Dr. Tilley includes atrophic rhinitis in his book, and perhaps finds sufficient justification in the fact that some authorities opine that there is a distinct relationship between accessory sinus disease and atrophic rhinitis. Still, having introduced this disease, it would have been better to have described it more in detail It is, however, to diseases of the accessory sinuses that Dr. Tilley chiefly directs his readers' attention, and he gives a detailed list of 16 cases of frontal sinus operation and alludes to 200 cases of antral disease that he has seen. Dr. Tilley's book is one which, as we have said, will be most useful, though he assumes, perhaps, at times that his readers have a wide knowledge of the subject.

Introduction to Medical Jurisprudence. By WILLIAM MCCALLIN, M.D., B.Ch. R U.I., D.P.H. Camb., Barrister-at-Law. London: Baillière, Tindall, and Cox. 1901. 8vo. Pp. 160. Price 4*s*

THIS work occupies a position between the large text-book on the one hand and the small examination cram-book on the other, and thus, though perhaps its scope of usefulness is but limited, it may be considered worth buying by most general practitioners, who do not often require a large work of reference on this subject. More than half the book is devoted to the essentials of medical jurisprudence, and the information is given in a concise, lawyer-like way with a minimum of comment by the author. The articles on Death, Post-mortem Examinations, Identity, Infanticide, Insanity, and Wills are thoroughly practical and useful, though they are all very short. The latter half of the book deals with Toxicology. Only the poisons that are most frequently fatal are described, and those are arranged very conveniently in alphabetical order, while at the end of the list is a table of doses of the usual remedies employed as antidotes. The general remarks which precede the description of the poisons are worth reading, containing as they do legal definitions of terms used in connexion with criminal poisoning and the essential points of the law relating to the sale of poisons. The brief articles on Food-poisoning and Ptomaines are too sketchy to be of much service, however, and it would be as well, too, if the author had given a little more information about edible and non-edible mushrooms. Having in mind the recent criminal trial in Paris known as the "Gouffé Murder Trial," in which the counsel for the accused, Gabrielle Bompard, urged that she was acting under the compulsion of the post-hypnotic suggestions of her paramour, we looked in vain for the opinions of Dr. McCallin on the bearing of hypnotic suggestion on medical jurisprudence.

Sooner or later English lawyers will have to face the question of how far hypnotism can be employed as a criminal agency. We think that the author might have mentioned hypnotic suggestion under several of his headings—notably under Rape and Assault. Dr. Luys in 1891 definitely declared that violations may certainly take place in the catalepsy induced by the hypnotist. Others than medical men are able to induce *hypnotic sleep, and when the* knowledge of this influence is more widespread there can be little doubt both that hypnotic suggestion will be used by unscrupulous persons and that malefactors will plead post-hypnotic influence as an excuse for their behaviour, just as many criminals now feign and plead insanity. Any medical man may one day find himself in court as an expert witness, and he would do well to be acquainted with the possibilities of injuries to the person committed while in that state of partial insensibility which we know as hypnotic sleep.

LIBRARY TABLE.

Materia Medica, Therapeutics, Medical Pharmacy, Prescription-writing, and Medical Latin By WILLIAM SCHLEIF, Ph.G., M.D., Instructor in Pharmacy, University of Pennsylvania. London: Henry Kimpton. 1901. Pp. 354. 8vo. Price 7*s* 6*d.*—This is a text-book on materia medica intended, we suppose, for American students of medicine; it contains "in a concise, definite, and assimilable form the essential knowledge required in the most complete college courses." There are no references in it to the British Pharmacopœia, and for this and other reasons the book will be found of no service to students preparing for examination in any university or college in the United Kingdom. Anxious as we are to do justice to the volume we cannot altogether congratulate the author on his arrangement of the subject-matter. There are the usual tables of doses, of poisons and their antidotes, of incompatibilities, and there is the usual instruction in prescription-writing The remedies are arranged for description under headings indicating their most important therapeutic use, and thus we find under the heading "Alterative" such differing medicines as iodine, cod-liver oil, sarsaparilla, and colchicum. Only in a few cases is the method of laboratory preparation of a medicine described and the ingredients of even commonly-used pharmacological preparations are in many cases omitted altogether. Thus if we look up paregoric we find it, of course, under its American name of tinctura opii camphorata and we read that "it contains opium gr. ij. to fl. ℥j. and a variety of other ingredients." To learn all about the therapeutics and pharmacology of, e.g., potassium and its salts it is necessary to consult six different parts of the book. There are two indices given, one "general" and the other "therapeutic," but it would be better if there were but one, for the work of reference is not as simple as it should be. There are a few pages devoted to the teaching of practical anæsthesia, but the information here, as for the most part elsewhere in the book, is scrappy and incomplete. We regret that we cannot recommend the book to British medical men with any degree of confidence.

Manners for Girls. By Mrs. HUMPHRY ("Madge" of *Truth*), author of "Beauty Adorned," &c. London: T. Fisher Unwin. 1901. Pp. 139. Price 1*s.*—This is a little book on the purchase of which girls might do worse than expend 1*s.*, for it contains a number of useful hints in little matters of etiquette adapted to all sorts of occasions which might prove of much assistance to those about to embark in society. It is short, sensible, and to the point, and young girls might do well to read it because it hits off numerous situations which, without the exercise of a little promptitude and judgment, are occasionally apt to prove embarrassing.

Lip-Reading: What it Is and What it Does for the Partially Deaf. By ISABEL POLLOCK. London: Simpkin Marshall, and Co. 1901. Pp. 12. Price 6*d.*—Miss Pollock's intention in writing this pamphlet is to help in some small degree to arouse the outside world to practical interest in a process by which half the disabilities of the deaf person can be removed. She points out that the oral system of teaching the deaf, though well known in the educational world, has not received the smallest attention from the public, and she urges that this neglect should be rectified. Writing from personal experience Miss Pollock testifies to the incalculable benefit which she has derived from lip-reading. She lost the pain of being left out of social intercourse and the power of lip-reading brought "nothing short of a new life" to her. If they are able to lip-read deaf persons can not only share in the conversation around them, but can retain posts of responsibility and discharge the duties effectively, though quite unable to hear a word that is said. Nor is the art of lip-reading so difficult to acquire as is generally supposed; according to Miss Pollock anyone with ordinary ability and patience can acquire it in a few months. In these circumstances medical men will do well to bring the matter before any deaf patients they may have with perhaps greater insistence than they now employ.

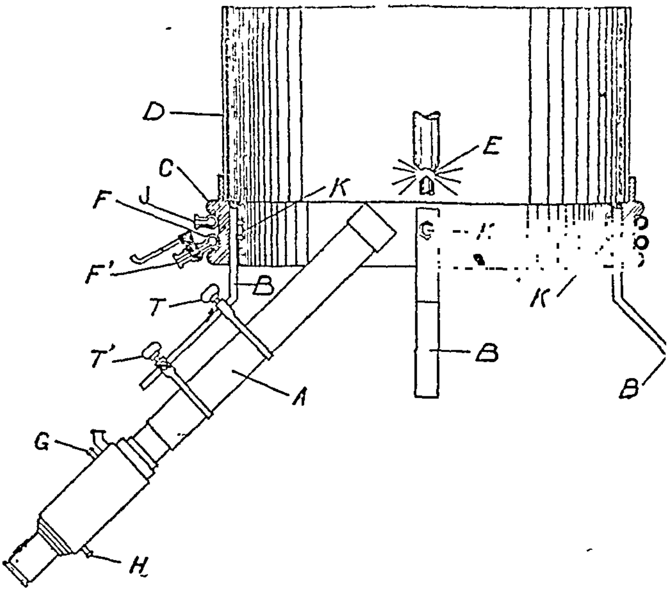
JOURNALS AND MAGAZINES.

The Journal of Physiology. Edited by Sir MICHAEL FOSTER, F.R.S., and J. N. LANGLEY, F.R.S. Vol. XXVI. No. 6. London: C. J. Clay and Sons. June 14th, 1901. Price 6*s.*—The articles contained in this number of the *Journal of Physiology* are the following: 1. The Conditions of Action of "Trypsin" on Fibrin, by H. M. Vernon, M.A., M.D.Oxon., Fellow of Magdalen College, Oxford; with two figures in the text. Dr. Vernon's experiments show that trypsin is very rapidly destroyed by sodium carbonate, an active extract kept at 38° C. with 0·4 per cent. Na_2CO_3 having about 65 per cent. of its ferment destroyed in an hour. 1 per cent. Na_2CO_3 destroys over 80 per cent. and pure water may destroy over 30 per cent. in the same space of time. The statement made by Schütz that the rate of digestion varies as the square root of the quantity of ferment present is confirmed by Dr. Vernon. 2. Intestinal Absorption of Maltose, by E. Waymouth Reid, Professor of Physiology in University College, Dundee. Professor Reid shows that in the normal gut the uptake of maltose and glucose is independent of the relative rates of diffusibility of these substances. 3. Transport of Fluid by certain Epithelia, by E. Waymouth Reid, Professor of Physiology in University College, Dundee, with seven figures in the text. 4. Observations upon the Chemistry and Heat-rigor Curves of Vertebrate Muscle, involuntary and voluntary, by Swale Vincent and Thomas Lewis, with 10 figures in the text; from the physiological laboratory, University College, Cardiff. 5. On the Presence of Nerve Fibres in the Cerebral Vessels, by William Hunter, M.B., C.M. Aberd., with two figures in the text. By *intra-vitam* injections of saturated aqueous solutions of methylene blue till the animal died the presence of a dense plexus around the vessels is demonstrated and the appearances presented are depicted in two wood-cuts. 6. The Conditions that Underlie the Peculiarities in the Behaviour of the Coloured Blood-corpuscles to Certain Substances, by G. N. Stewart, M.A., M.D., Cleveland, U.S.A. This article is the outcome of experiments made to determine whether the power of selecting certain substances by cells from surrounding liquids and of rejecting others depends upon the vitality of the corpuscles or upon a certain physical structure or chemical composition of the cell envelope or cell substance. The author attributes the power to the structure of the corpuscles in the case of the white corpuscles of the blood and in part to the nature of the envelope and not to their vital qualities. 7. The Colorimetric, Determination of Hæmoglobin, by John Haldane, M.D.Edin. F.R.S., with one figure in the text. The number also contains the Proceedings of the Physiological Society.

IMPROVEMENTS IN THE APPARATUS USED FOR THE TREATMENT OF LUPUS BY LIGHT RAYS.

THE remarkable results obtained in the light-ray treatment of lupus have naturally directed attention to the design of the apparatus with the view to its improvement in many important details and to increase its convenience of adaptation. Primarily the apparatus consisted of a series of lenses and water chambers through which the intense rays of the arc light travelled. The rays were thus not only focussed but separated—the light rays from the heat rays. The water chambers served to absorb the heat rays and the lenses to focus the light rays. One of the chief difficulties met with in the apparatus is that of providing, so to speak, absolutely water-tight compartments. Leakage was a constant source of trouble, and only the best construction is calculated to obviate the effects of contact with water constantly varying in temperature. Further, not only is leakage to be avoided, but the lenses ought to be easily removeable for the purpose of cleaning them. Now, however, that the importance of the treatment has been established

FIG. 1.

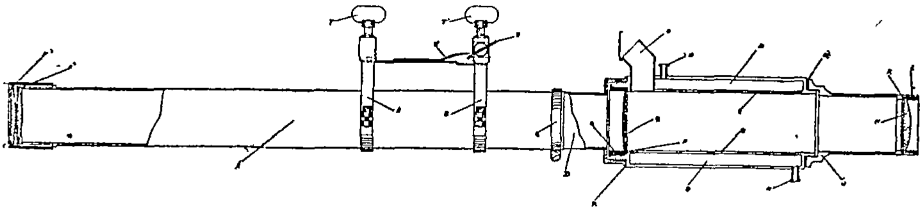


The electric light apparatus with one collector.

more attention has been paid to these points and an apparatus has been constructed, excellent both in workmanship and design, in which the structural defects just indicated no longer exist. The description of this improved apparatus will therefore be of interest.

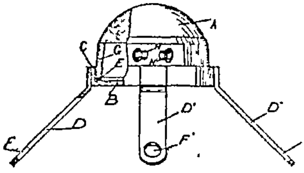
First of all, the arc lamp used is of the direct current type, taking from 50 to 80 ampères at 70 volts pressure and generating a light of approximately 30,000 candle-power. As will be seen in Fig. 1, the arc E is surrounded by a ring of metal, O, which is rigidly suspended from the ceiling of the building at a height of from six to seven feet from the floor. The lamp is shaded by a cylindrical hood D (Fig. 1). Four sets of crystal collecting lenses, one of which is shown in the figure (A) are mounted on brackets B, B, B, which are attached to the ring C and can be adjusted vertically by the bolt at K in order to place them in the best position for collecting the light. Outside the ring O are placed two pipes F, F′ which provide for a system of circulation of cold water. In Fig. 2 the structure of the collecting tube will easily be seen. It contains four rock-crystal lenses. At the end nearest to the arc light are two lenses F, F in tubes which slide on to the body of the collector like a telescope cap which can be removed for cleaning. Lower down will be seen two clamps for attaching the apparatus to the brackets T, T′ in Fig. 1. These brackets are so made as to allow of an adjustment by means of screws so that any irregularity in the burning of the lamp may be compensated for. Further adjustment may be made by means of the screw V which provides for deflecting the collector in the opposite plane (Fig 2) In practice the adjustment screw T is [illegible] Fig. 2, a draw tube B slides which can be fixed at any position by the clamp S which enables a focus of the light to be made and consequently the size of the image to be adjusted. This draw-tube carries a pair of rock crystal lenses G and H, and the space between these lenses is filled with distilled water to absorb the heat rays from the light, a tube O with a hinge cap being provided for the purpose of filling. The greater portion of this absorption chamber is jacketed so that a constant stream of water may be kept up through the nozzles N, N and thus keep the absorption chamber cool. All the lenses can be removed for cleaning. The joints are perfectly water-tight, consisting of a rubber ring against which the lenses are gently but firmly pressed by means of a screw. The joints can at any time be renew[illegible] of fresh rubber washe[illegible] advantages of this [illegible] of the apparatus is the "compressors," as illustrated in Fig. 3. These consist of two rock crystal lenses with a space between them for the circulation of water. The lens B is parallel, while the outer one, A, is bull's-eye shape, the curve being adjusted to fit that portion of the body under treatment. The water is conveyed through the tubes represented at H, H. D, D, D are arms or handles which enable the operator to hold the compressors, without obstructing the view through the lens B. The compressors may be attached to the patient by elastic bands (Fig. 3). This piece of the apparatus is constructed in the same way as are the lenses in the tube—that is to say, the lenses may be easily removed and cleaned and the rubber washer may be easily replaced. In Fig. 4 will be seen a special form of compressor with holder for treating surfaces such as the cornea of the eye, but in ordinary practice the forms of compressors shown in Fig. 5 are found to be most useful (Figs. 4 and 5). The water circulation is established by drawing the supply from a tank situated at a considerably higher level than the apparatus from the tap F (Fig. 1), indiarubber connexions being made throughout for the water jacket. The water enters by the nozzle G (Fig. 1) and flows out of the nozzle H to one of the nozzles of the compressor. Thence it flows through the compressor to the exit pipe and thence to the waste-pipe.

FIG. 2.



The collector.

FIG. 3.



The "compressors."

This apparatus is admirably adapted for the purpose in view. It is free from the annoyance of leakage and is so designed that the lenses may be easily removed and cleaned, while adequate provision is made to give the apparatus stability and support during its application for treatment. We have inspected a type of this apparatus, which was under construction at the engineering works of Messrs. R. and J. Beck, Limited of 68, Cornhill, E C., to whom we are indebted for the illustrations in the text. These instrument-makers have also designed an apparatus for use with the sun, consisting of a water-lens with a thin glass back and a curved front filled with a solution of methyl blue. This lens is suitably and strongly mounted and it may easily be cleaned. The compressors are the same as those which are used with the electric light apparatus The crystal collectors cost £15 each and the ring containing the lamp with copper circulating pipes about half that amount, while the compressors cost about a guinea a-piece.

Various forms of compressors.

PREVENTION OF TUBERCULOSIS.—A meeting was held at the Guildhall, Gloucester, on July 2nd, under the presidency of the Mayor, for the promotion of the scheme to establish a free sanatorium for Gloucestershire, Somersetshire, and Wiltshire for the open-air treatment of consumption. Interesting addresses were delivered by Dr. R. Maguire (physician to the Brompton Hospital for Consumption) and Dr. L. A. Weatherly of Bath. The meeting passed resolutions in support of the project and for the appointment of a committee to advance its interests locally.

THE LANCET.

LONDON: SATURDAY, JULY 13, 1901.

Epsom College.

THE twenty-eighth festival dinner of the Royal Medical Benevolent College, Epsom, the report of the proceedings at which will be found in another column, was held on Tuesday night last at the Hotel Cecil. Every nerve had been strained by those responsible for the finance and management of the College to obtain from and through their guests a large accession of pecuniary support. The owners of some of the best-known names in medicine were present and in Lord ROSEBERY, the President of the College, an ideal chairman was forthcoming. The interest which THE LANCET has always taken in Epsom College makes us very glad to be able to report that the outcome of the dinner was the substantial addition of over £4000 to the funds. The pressing needs of the day have thus been provided for by the generosity of a few members of the public and of the medical profession, but it must be pointed out that only temporary necessity can be met with such a sum as £4000, and that what is required is a regular and substantial endowment commensurate to a certain extent with the expenditure necessitated by the foundation. Dr. HOLMAN, the treasurer of the College, and Mr. LAMB, the secretary, have year after year with unwearying energy striven to bring this fact before public attention, and as far as lay in our power we have assisted their efforts. Some measure of success has been attained by persistent struggle, but we wish our readers fully to understand that the handsome result of the collection made at the recent dinner in no way absolves them from the obligation of subscribing to the funds of Epsom College.

Epsom College was founded with a twofold object. There was to be a public school where the education should be as good as that provided in any secondary institution in the kingdom. Secondly, certain provision was to be made for a limited number of unfortunate medical men or their widows, while foundation scholarships were to be offered to the children of such medical men as were unable during their professional career to make provision for their families. This double aim of the institution has been found to involve the management in something of a dilemma, the difficulty of which has recently become more obvious than ever. It is expressed in the full title of the institution—the Royal Medical Benevolent College. Epsom College is a public school open to, and attended by, boys who generally go to an English public school; their parents are of the same class and have the same range of income. Therefore it militates against the interests of the school to be labeled "medical" or "benevolent." The parent who pays full fees for his children because he can afford to do so does not care to have it appear that he is educating them with the assistance of charity. The parent, again, who does not belong to our profession sees no inducement in the word "medical" to send his children to Epsom College. For which reasons it is clear that the adjectives "medical" and "benevolent," as Lord ROSEBERY said in his capable and sympathetic address, would be better out of the title of the institution. They are cumbrous, they are not wholly accurate, and they do not serve the best interests of the school. But, and it is a large but, Epsom College has a very valuable and delicate trust to discharge. The kernel of the founder's idea was to benefit the medical profession, and no alteration in the title or the working of the College can be sanctioned, with fairness to PROPERT or the medical profession, which might endanger his great design. PROPERT was profoundly moved by the fact that a very large proportion of medical men, carrying their lives in their hands as literally as does the soldier on the battlefield, are struck down before they can make adequate provision for their families. He desired to shelter some of the unfortunate widows, to give peace to the last days of a few luckless professional brethren for whom circumstances had proved too strong, and to educate a proportion, if only a small proportion, of the children of medical parents who would otherwise have no chance of receiving the training that they were entitled to expect. These were the founder's noble wishes; and as long as the adjectives "medical" and "benevolent," by keeping his design before the minds of subscribers, help to provide funds to carry out the original charitable scheme so long those adjectives must remain.

There is a perfectly simple remedy. The College, under a recent Act of Parliament, possesses the power to alter its name to Epsom College, and the authorities will make this change directly they know that their pecuniary support is so large and so certain that the interests of those whom it was designed to benefit charitably are safe. We do not think that the £50,000 which the treasurer in an admirably clear speech asked to have given to him is likely to be forthcoming in the lump. Many less worthy objects have been munificently endowed in this way, but we see no grounds for taking a more sanguine view at the present moment. It is increased income to which Epsom College must look. If the College were supported, as it should be, by every medical man in the kingdom the regular influx of subscriptions would be so large that the certain income would allow of the titular modification which everyone admits is almost necessary. And not only can the medical profession help by subscribing; they might well make it one of their duties—nay, one of their pleasures even—to proselytise in the interests of the College. Epsom College, from the charitable point of view, has claims upon the public as strong as are its claims upon the medical profession. Ours is not a well-paid calling and the social conditions of medical life make it almost impossible for the medical man to save from the beginning of his career. There are circumstances in medical practice—we refer particularly to general practice—which make it almost necessary for the medical man to be married when young, yet many cannot expect success until middle age is reached. If death should occur before success comes, what provision can the bread-winner make for his family save a small life insurance? None. This is a fact which might well be brought by all our readers before their patients. It is a gratifying truth that we sometimes meet with sufferers who are ready to recognise that the ministrations which they have experienced are not really paid for by discharge of a bill. They are willing to see that medical service is not simply trading and that the intimate relations between the sick and the medical attendant are not just those of employer and employed. Every opportunity might well be taken to point out to these just persons that to endow Epsom College is a particularly apt manner of wiping out a debt to which no formal claim is made but which their own consciences press upon them. We own that we should like to see the medical profession at large sturdy beggars in the interests of Epsom College.

◆

Stocks and Crossman v. Watson.

THE above action was tried in the King's Bench Division of the High Court, before Mr. Justice BRUCE and a special jury, on June 26th. It was originally a claim for payment of account for professional services rendered by the plaintiffs to the defendant—a licensed victualler—and members of his family. In the ordinary way the hearing would have taken place at Wandsworth County Court, but the defendant, in *addition to disputing the claim, counterclaimed for damages* (£250) on the ground that one of the plaintiffs—Mr. F. STOCKS—had not treated him with ordinary care and skill; and consequently, pursuant to the Judicature Act, 1873, Section 99, it was ordered that the action should be transferred to the High Court of Justice on the ground that the defence or counter-claim of the defendant involved matter beyond the jurisdiction of the county court.

On Sept. 28th, 1900, the defendant Mr. WATSON met with a bicycle accident, and besides other injuries he sustained damage to his shoulder. Mr. STOCKS was called in on the same day and, according to his evidence, he made the ordinary examination for dislocation of the shoulder-joint but failed to detect evidence of luxation. Some time in December Mr. STOCKS found that the joint was dislocated, and he made an ineffectual attempt to reduce it. He did not consider it advisable in the defendant's state of health to give an anæsthetic, and in this he was supported by the judgment of Mr. H. H. CLUTTON who examined the patient on Jan. 4th, 1901. Both Mr. CLUTTON and Mr. VICTOR HORSLEY, who were called for the plaintiffs, were of opinion that if Mr. STOCKS at the first examined the defendant in the manner he described he must have found the dislocation if there were one; that the injury to the shoulder might have predisposed it to dislocation; and that an injury subsequent to the bicycle accident, such as a fall out of bed or injudicious pulling at the arm by someone, might have produced it. On the question of the character of the examination made by Mr. STOCKS on Sept. 28th there was a direct conflict of evidence. The defendant and his wife said that the rotatory movement carried out by Mr. STOCKS was done whilst the defendant had a covert coat on. On the other hand Mr. STOCKS averred that he used the customary methods whilst his patient was stripped. It was admitted that as a consequence of the swelling on the days following the accident the diagnosis would be more difficult. The summing-up left nothing to be desired. The learned judge said that the main issue to be determined was: Did Mr. STOCKS use ordinary and reasonable care in his examination on Sept. 28th? Because if he did it seemed impossible that he could have failed to detect a dislocation if it existed. The jury replied in the affirmative. The verdict was thus in favour of the plaintiffs. As regards the counter-claim, costs would necessarily follow on the High Court scale, and on the direct claim of the plaintiffs the judge said that he would give a certificate. The action was taken into the High Court at the instance of the plaintiffs, although the amount sued for by them was less than £50 and thus within the limit for county-court actions. From the gravity of the issues involved it was clearly a case to be tried in the King's Bench.

It is well known that simple dislocations, and especially of the shoulder, are not always diagnosed at the time, but the exceptions are few and far between. A medical man of ordinary knowledge and attainments could scarcely with due care fail to detect a dislocation of the shoulder. The limitation of movement of the arm, the alteration in length, and the hollow tension of the deltoid are alone sufficient to determine the nature of the injury. As regards the value of the evidence given at the trial we may say, without in the least degree questioning the *bona fides* of the defendant and his witnesses, that a medical man would be more likely to recall accurately the nature of his examination and the conditions under which it was made. To have found for the defendant the jury must have come to the conclusion that they could not rely upon the testimony of Mr. STOCKS, and without that the corroborative testimony of Mr. CLUTTON and Mr. HORSLEY would have been of little avail. We entirely subscribe to the verdict and congratulate Mr. STOCKS on the vindication of his professional reputation, which, after all, was his chief aim.

◆

The National Hospital for the Paralysed and Epileptic.

THE meeting of governors of the National Hospital for the Paralysed and Epileptic, Queen-square, which took place on Saturday, July 6th, adopted unanimously three resolutions calculated to render effective the findings of the report recently referred to in our columns.[1] By the first resolution the report was adopted; by the second resolution it was decided to appoint a committee to carry into effect the recommendations of the report; and by the third resolution the constitution of this committee was decided upon. It is to consist of nine members, four of these to be appointed by the committee of governors elected on March 23rd, three by the Board of Management, and two by the medical staff. We cannot help thinking that the medical staff has exercised too much forbearance in being satisfied with a smaller representation in this committee than the Board of Management. The staff has shown all through this unfortunate but most necessary controversy an interest in, and regard for, the best interests of the hospital and a knowledge of its requirements to which the actions of the Board of Management have shown them to be quite strangers, and it would probably have been much to the advantage of the charity if the numbers of Board and staff representatives had been reversed. We are informed that even at the meeting of the Board specially convened to receive the report the necessary quorum could not be obtained and the meeting had to be adjourned; and at the meeting on Saturday last, at which the great majority of the staff was present, the Board was represented by the chairman and one other member, although it is true that two other members of the Board were present for a few minutes but left before the resolutions were carried. How the long-suffering governors of this institution regard such "slackness" on the part of their representatives we cannot tell. To most other people it looks like callous indifference to duty and an almost studied insult to the electorate.

---

[1] THE LANCET, June 29th, 1901, pp. 1837 and 1855.

It cannot be denied that the duty imposed upon the committee first appointed is a most onerous one. No one who has not carefully studied the wonderfully tortuous rules and by-laws which have gradually been imposed on this charity can be at all aware of their nature. They seem to have been skilfully framed to exclude the so-called governors from obtaining any effective voice in its management, and the alterations which will have to be made must be both numerous and radical. The abolition of the office of secretary-director, followed as it has been by the resignation of that official, and the admission of representatives of the medical staff to the Board of Management, which that body has already sanctioned, will no doubt do much towards a healthy reconstruction, but the committee, we venture to think, will find many things to abolish and many more to amend. If the statement made by the Chairman of the meeting held on July 6th is to be regarded as expressing the deliberate opinion of the Board, that body must be singularly obtuse to the censure conveyed in almost every line of the report, and in that case the committee may find in the representatives of the Board a solid body of resistance to even moderate proposals of reform. It is almost incredible that a member of the Board should have the effrontery, in face of a report which condemns the conduct of the hospital in almost every particular except the treatment of the patients for which the medical staff was responsible, to say that "the condition of the hospital was good and the management on the whole satisfactory." We do not wonder that an energetic protest was made on behalf of the medical staff against such a statement. What the members of the staff alleged in their original letter to the governors was quite the contrary of this, and the report of the commission shows them to have been right.

We can now only await the action of the committee. We trust that the effect of their revision of the rules and by-laws and of their careful study of the report may be to establish this useful charity on such a basis as to give everyone connected with it, whether in a medical or any other capacity, a pride and interest in it which will ensure for it a career of ever-increasing honour and usefulness.

Annotations.

"Ne quid nimis."

FASHION AND THE SUN.

THE alarming accounts of deaths from heat in New York, not, we are happy to think, entirely free from the exaggeration that spices most newspaper sensations as served up in America, have naturally aroused fears that this country would receive the heat-wave and furnish victims to an unusually high atmospheric temperature. In countries where great heat is regularly expected at certain seasons life is adjusted to meet the conditions. Business is abandoned in the hot hours; leisure, few clothes, sleep, and appropriate drinks reign in the place of affairs, which are relegated entirely to the cooler portions of the day. In England, because great heat is so occasional and because we are slow to change our customs, the inconveniences of a high temperature bring no attempt at alleviation. No changes are made in the hours of business and business men prefer to perspire and to fret beneath a silk "topper" and a frock coat, though they would prosper no less and be far more comfortable in flannels and a "straw." The learned professions show no wider sense of what is due to climatic changes. Clergymen, lawyers, and our own profession alike preserve the proprieties and in black-coats sweat to their satisfaction. Women alone, whether guided by the instinct with which they are credited or by the reason in which they are commonly thought deficient, show men in this matter how suitably to adapt costume to climate and to remain cool, active, and comfortable, though the sun shine never so fiercely. Do men want to vaunt their superior physique that they make such a contrast between the heavy trammels of their own costume and the easy coolness of that of their wives and daughters? On one side a black coat, top hat, stiff shirt, and black boots; on the other a light bodice, open or with only lacing at the neck, soft cool skirts, open-work stockings, light shoes, and a parasol. No one doubts which looks better; is there any more hesitation in declaring which is healthier and better adapted to activity in a hot atmosphere? We do not suggest that Cornhill should quiver with parasols, or that the Stock Exchange should rustle with the flimsy skirts of hurrying brokers, but why should not light flannels and broad light straw hats be universally adopted in hot weather? Men would be better able to attend to their affairs and, a by no means unimportant point, would need far less to drink, for they would perspire less. Stiff shirts and stiff collars should be put away in hot weather. When they absorb perspiration they become ridiculous and when they preserve their rigidity they are unhygienic.

PROPOSED EPILEPTIC ASYLUM NEAR BLACKBURN.

AT the meeting of the Manchester Board of Guardians on June 26th, a communication was read from the Chorlton and Manchester Joint Asylum Committee pointing out that application had been made to the Local Government Board for their approval of the purchase of about 165 acres of land near Blackburn for £13,627, for the erection of an asylum for invalids and epileptics. Alderman McDougall said that after long seeking a suitable site had been found. The Local Government Board was anxious that the scheme should be proceeded with and the building would soon be commenced. It was the intention of the Joint Committee to place the imbeciles and epileptics in separate departments of the asylum. The chairman hoped that the Prestwich Union would join the scheme. Many sites had been inspected but were unsuitable, and Alderman McDougall thought that they had been lucky to find one on the Manchester side of Preston. In commenting on this the *Manchester City News* says that the proposal should be considered with care and seems to think it hard that "the Joint Committee *is solely responsible to the Local Government Board* and that the ratepayers have only an influence when the mischief is done," also that the price per acre is more than double that asked for Heaton Park. The buildings, it thinks, will cost "anything up to £250,000," and "probably £10,000" will be required for annual maintenance. The number for whom provision is to be made is about 500, who are, as the paper says, "already being housed and tended in workhouses and asylums." Without concurring in the views just given—it being quite clear that increased provision is needed for these unfortunate people—some moderating influence might be well employed in distinguishing between what is necessary and reasonable in the estimates for such institutions, and what is unnecessary and extravagant. There is no doubt a delightful feeling of opulence among those who spend other people's money, the results of which may be seen in the furnishing of, e.g., some school board offices or the board-rooms of limited liability companies. It is evidently very difficult for persons in this position to resist the inclination to lavish expenditure, regardless of mere ratepayers or shareholders.

UNUSUAL SYMPTOMS OF A WOUND OF THE SPINAL CORD WITH PARTIAL RECOVERY AFTER OPERATION.

IN the June number of the *Journal of Nervous and Mental Diseases* Dr. Joseph Sailer records an interesting case of an injury to the spinal cord inflicted by a bullet during the Cuban war, and the result of operation three years later. The case is of interest in several respects—viz., as regards the presence of curious sensory phenomena and the results of operation. The patient was an officer in the Cuban army, aged 31 years, and he was wounded by a Mauser small-calibre bullet on Nov. 2nd, 1896. The bullet entered one centimetre to the left of the right nipple and passed out 2·5 centimetres to the left of the spinous process of the twelfth dorsal vertebra, having penetrated the lung, the liver, and the spinal cord. The wounds of entrance and exit healed in the course of a week without suppuration. The only serious results were those due to injury of the spinal cord. Immediately after the wound there were complete paraplegia and intense pain in the back, while there was loss of sensibility in the lower half of the body. Atrophy of the lower limbs followed and bed-sores developed over the sacrum, buttocks, and ankles. There were also severe paroxysmal pains in the thighs and lower portion of the abdomen. To relieve the pain the patient took morphia hypodermically and thus acquired the morphia habit. On May 3rd, 1898, he was admitted to the Presbyterian Hospital in Philadelphia in the following condition. There was some motility in the left leg as regards movements at the hip and knee. There was no movement at the ankle or of the toes, but a slight tremor developed in the toes upon effort. The knee-jerk was greatly exaggerated, but there was no ankle-clonus or plantar reflex. In the right leg there was slight flexion of the thigh, due to contraction of the ilio-psoas muscle and the only movement possible at the hip was slight adduction. The reflexes were abolished in the right leg which was totally anæsthetic below the upper third of the thigh. Just above this line there was a zone of hyperæsthesia, three inches broad, around the thigh. In the left leg there was total anæsthesia exactly to the same extent, but sensation was normal above that. In November, 1899, the patient began to suffer from lightning pains about the thighs and lower part of the abdomen. These were severe and did not respond to drugs, and as the patient was getting weaker laminectomy was performed. The arches of the tenth, eleventh, and twelfth dorsal and first lumbar vertebræ were removed, exposing about four inches of the spinal cord. The dura mater was found to be greatly thickened. It was opened and freed from adhesions to the pia mater in and about the lower part of the incision. About a pint of cerebro-spinal fluid escaped freely during the operation. The spinal cord appeared normal to inspection and palpation. The wound healed without trouble, but for the first four weeks the pains continued as before and were even somewhat intensified. Improvement followed after this as regards movements of the hips and knees, but the ankles and toes remained practically incapable of movement. There remained, however, a total anæsthesia over the sacral area and partial anæsthesia of the perineal region. Allochiria of the legs was discovered 39 days after the operation, while improvement was still in progress, and lasted only three days.

BLINDNESS DUE TO DRINKING BAY RUM AND OTHER LIQUIDS CONTAINING METHYL ALCOHOL.

AT the annual meeting of the American Medical Association held in June Dr. H. Moulton described the case of a man who drank bay rum and next day had an uneasy sensation about the eyes followed by vomiting. He suffered from dizziness, retching, and gastro-intestinal symptoms for two days after this. Vision became feeble, especially at dusk (*hemeralopia*), and ophthalmoscopic examination showed œdema of the optic papilla and retina. Finally total blindness ensued, the discs of the eyes now showing the appearance of optic atrophy. Dr. Moulton points out that similar symptoms may result from "Jamaica ginger"—a liquid preparation which contains about 95 per cent. of methyl alcohol. Dr. Ray of Louisville cited a case under his observation where blindness began on the second day after drinking methyl alcohol. There was œdema of the optic nerve and retina. Blindness ensued and lasted three or four weeks, when the power of vision gradually returned, central vision being the last to reappear. Dr. Woods of Baltimore described cases of blindness from Jamaica ginger which on inquiry was found to consist almost entirely of methyl alcohol in which the active principles of ginger were in solution. Dr. Wood of Chicago referred to an instance where several persons had partaken of the same liquid but only one suffered from the above after-effects. He pointed out that an idiosyncrasy may exist in some cases.

SEWAGE DISPOSAL AT BURNLEY.

A REPORT recently presented to the Highways and Sewage Committee of the County Borough of Burnley speaks strongly in favour of the bacteria bed system of sewage disposal lately adopted there. The result is of special interest in view of the fact that the staple industry of the town is cotton-weaving, and in addition there are also spinning mills, iron works, two dye works, and a tannery, the trade effluent from the two last-named being discharged into the sewers. Various chemical methods were tried, but without satisfactory results. Ultimately bacteria beds were adopted which proved a success both from the economical and hygienic point of view. In the report it is stated that from a careful perusal of the figures it is confidently felt that a very considerable saving is effected by the adoption of the system now in use as compared with that of chemical precipitation and land irrigation formerly practised at the Burnley sewage works. As to the effluent, it is stated, according to incubator tests made with the second contact-bed effluent, that the indications are that the purification was sufficiently complete to allow of the discharge of the effluent into any stream without fear of objectionable contamination. Fish placed in this effluent thrived and since November last have presented a healthy and flourishing condition, although they were supplied with nothing but the effluent from one or other of the secondary beds. It is interesting to note in this report that although the temperature of the atmosphere fell as low as 19° F. on one occasion yet the temperature of the tank effluent and of the first contact-bed effluent and of the second contact-bed effluent did not fall below 45°. Of course, the microbic action taking place in these beds is accompanied by distinct evolution of heat and it is owing to this fact that the temperature of the beds, and consequently also of the effluents, is not affected by atmospheric changes to any sufficient extent to interfere with their efficient working or with the development and growth of the bacteria required for purification. The results of the whole scheme, in fact, are such as to lead to the belief that it will prove an efficient one, and that the treatment of the sewage of the borough will be carried out in a more satisfactory manner and with less cost by this system than it could be by any other which has come under the notice of those entrusted with the solution of the problem. With this sort of evidence coming to hand almost day by day the probability is that the disposal of sewage by chemical means will sooner or later be abandoned.

THE NEW FACTORY AND WORKSHOP BILL.

RUNNING through the Government Bill to Amend the Factory and Workshop Act there is a tendency to substitute the local for the central authority in respect to the control and the inspection necessary to carry out the provisions of the law. Whatever abstract arguments may be adduced in favour of local government, practical experience clearly shows that in respect of sanitary questions small local bodies elected by the ratepayers are not to be trusted. For example, what has been done to prevent the terrible pollution of the Irwell and other Lancashire rivers? If the law were applied this pollution would not occur. Its application, however, is entrusted to the local governing bodies, but the manufacturers, who are the principal transgressors against the law, dominate at the elections and therefore year after year pretexts are discovered for not applying the law. Any legislation which appears to interfere with a local industry is likely to be resisted by the authorities elected in that locality. It is true that such interference has often proved to the advantage of the industries in question. It has led to the utilisation of what were considered waste products, and by improving the health of the workpeople has resulted in an improvement of the work which they are able to perform. Nevertheless, such measures are generally at first strenuously resisted. Whatever immediate advantage exists is fully appreciated; those that may result from a change are considered problematical. Thus reform as a rule has to be enforced from without. According to Clause 11 of the present Bill the power to forbid the giving out of work to places injurious to health is taken from the factory inspectors and is handed over to the local authority. It is true that Mr. Ritchie has promised to add subsequently a clause providing that where a district council neglects its duty in respect to outwork and outworkers a Home Office inspector may interfere. But who will volunteer to call the attention of the Home Office to such neglect? And what delay this will entail. A local authority is not likely to encourage the exercise of a strict control over, and the occasional prosecution of, its largest ratepayers and most influential electors; yet they are not infrequently among the principal transgressors against the laws enacted for the preservation of public health. The factory inspector who was appointed by the Home Office could do his duty without troubling himself as to how the owners of the factories which he inspected would vote at the next local election. But if as proposed the factory inspector is henceforth to be appointed by the local authority he will soon find out that it is expedient not to offend influential electors. Such a change would be a decided step backwards. It is no use improving the law if the means taken for its application are to be rendered less efficacious.

MEDICAL EXCURSIONS TO GERMAN WATERING-PLACES.

As briefly mentioned in the letter of our Berlin correspondent, which will be found on p. 107, arrangements have now been completed for the making of annual excursions by parties of medical practitioners and students to the various watering-places and mineral springs of Germany and Austria. The excursions are organised by the Comité zur Veranstaltung Aerztlicher Studienreisen in Bade- und Kurorte, and the first of them will start from Hamburg in the last week of next September for a trip of 11 days' duration to various health-resorts on the coast and islands of the North Sea, eventually returning to Hamburg. The expenses of the whole tour (everything being included except wine) amount to £5. The names of intending excursionists must be sent by August 20th at latest to one of the honorary secretaries, Dr. W. H. Gilbert, Baden-Baden, and Dr. P. Meissner, Kurfürstenstrasse 81, Berlin, W., from either of whom every information may be obtained.

EARLY ITALIAN MEDICAL WORKS.

IN 1894 the Eleventh International Medical Congress was held at Rome and in 1898 there was an Italian exhibition held at Turin. At both of these meetings there was a special department illustrating the history of medicine. The various documents have now been carefully catalogued and in some instances reproduced in a carefully printed volume[1] edited by Signor Piero Giacosa. Much of the book is taken up with reprints of hitherto unpublished treatises by masters of the school of Salerno. Of these the Catholica Magistri Salerni contains some most interesting information. Thus we note that the Master says concerning a cold: "Coriza est opilatio narium cum reumate." Could anyone in fewer words describe better that most annoying of all complaints? The treatment, too, we are sure, will interest sufferers: "Suffumigetur de asa fetida, serapino vel opoponaco vel bombace vetustissimo accenso et extinto, vel de vino decoctionis malve, foliorum lauri, semine lini, fenugreci aut meliloti et olebani vel de ipso olobano posito sub carbone vel storace vel laudano vel quolibet panno involuto de amurca olei accenso ex extinto vel de cornu caprino similiter subfumigentur." Besides all these the patient can, if he likes, poultice his nose with an application made of ground-up beans and pig's gall, or, if he prefer it, with a cooked onion. It will be noted that many of the drugs for the "suffumigation" are aromatics and would have an antiseptic effect. There are among the other MSS. reproduced two treatises upon the baths of Puteoli. Both MSS. are in the Biblioteca Angelica at Rome. One is in prose and has no illustrations, the other is written in verse and adorned with illustrations of the various baths. Though the sentiments are unexceptionable, the poetry is not—e.g.:

> Inter opes rerum Deus est laudandum in illis,
> In quibus humane deficit artis opus.

The illustrations give views of the various baths. We should note that Piero Giacosa's text is accompanied by a large portfolio of magnificent photogravures, reproductions of pages of MSS., illuminations, and the like. The illustrated MS. in the Angelica library is said to be of the thirteenth century, and a similar one of the same date, also in verse, was recently purchased at the Ashburnham sale by Mr. J. Leighton of Brewer-street, W., who very kindly permitted us to compare the illustrations in his MS. with those reproduced in Signor Giacosa's work. They are practically the same, although there is a slight difference in the details. The Angelica MS. apparently deals only with the baths of Puteoli. The MS. in Mr. Leighton's possession gives the "Nomina et Virtutes Balnearum Puteoli et Bayarum." The following are the verses descriptive of Bath No. II.:—

---

De Balneo quod Sulphurata Dicitur.

[illegible]
[illegible]
[illegible]
[illegible]
[illegible]
[illegible]
[illegible]
Intrabis securus aquas, nam corpora pura
Quum semel accipiunt servant sine labe salutem,
Inspirant quocunque modo, non balnea culpes
Affectum virtutis ama; nam saepe videmus
Quod fugiunt nares fugat hoc a corpore morbos.

In conclusion we must congratulate both Signor Giacosa and the publishers upon the production of a most interesting book.

THE PATHOLOGY OF GENIUS.

IN the July number of the *Popular Science Monthly* Mr. Havelock Ellis continues his series of papers upon British Genius. The article now before us deals with the pathology of genius, and Mr. Ellis has collected some interesting facts Out of 322 cases where he has been able to ascertain accurately, or nearly accurately, the cause of death, lesions of the brain occurred 35 times and pulmonary tuberculosis, including the somewhat doubtful case of Purcell, 30 times. Other forms of lung disease are only mentioned 15 times and of these nine deal with asthma. This, however, Mr. Havelock Ellis rightly points out is probably spasmodic asthma which is in no sense a true pulmonary disease. Gout is mentioned 38 times, and the gouty geniuses were very remarkable. A disease which can claim for its victims such men as Milton, Harvey, Sydenham, Newton, Johnson, Savage Landor, W. R. Hamilton, and Darwin is, indeed, a very Cæsar amongst diseases Mr. Havelock Ellis propounds a somewhat ingenious theory as to the concordance of gout with genius. The gouty man views the world with, as it were, two different brains. When uric acid is circulating in his blood he is gloomy and introspective. When the acid is deposited in his joints his brain becomes abnormally clear. He thus exhibits well-marked mental periodicity. Gout, however, must not be considered the cause of genius, but given a highly endowed organism the gouty poison acts as a stimulus. As for insanity, of 902 eminent persons some 5 per cent. were insane. Epilepsy is mentioned as having occurred in only two cases—Lord Herbert of Cherbury and Sir W. R. Hamilton. Other nervous or neurotic conditions are, however, fairly common. Many men of genius stuttered, many were singularly awkward in performing actions requiring muscular coördination, and many were "neurasthenic." In fact, Mr. Havelock Ellis's researches go to show that genius exists in persons highly charged with nervous energy, but the energy is ill-balanced and not equably distributed throughout the organism.

ANNUAL DINNER OF THE ASSOCIATION OF BRITISH POSTAL MEDICAL OFFICERS.

THE ninth annual dinner of the Association of British Postal Medical Officers was held on July 3rd at the Hôtel Métropole, London, Dr. J. Walton Browne (Belfast), the President, being in the chair. There was a large attendance of members and guests, including several Members of Parliament; Sir Robert Hunter, solicitor to the Post Office; Mr. E. P. W. Redford, secretary to the Post Office in Scotland; Mr. Baillie Gage, solicitor to the Post Office in Ireland; Sir William Mac Cormac, Sir Joseph Fayrer, Sir Dyce Duckworth, Sir James Crichton Browne, Dr. Tatham of the Registrar-General's Office, and Dr. James G. Glover. After the usual loyal and patriotic toasts had been given Dr. Henry Fitz-Gibbon proposed "The Board of Education and other State Departments." Sir George Kekewich, secretary to the Board of Education, in reply, said that the Cockerton judgment had left behind it a certain amount of chaos, and had made it difficult for an official of the Board to speak on the subject of education. Dr. Tatham also responded. Sir James Crichton Browne, in proposing "The Houses of Parliament," said that as medical men they were in favour of gradual and orderly development, and deprecated all violent changes, which were really acute diseases of the body politic and tended to degeneration. They thought the House of Lords might open its doors a little wider than it did, and that the House of Commons might endeavour to remedy its habitual malady, which had been termed "logo diarrhœa." Mr. Eugene Wason, M.P., responded. Sir Joseph Fayrer then proposed "The Royal Colleges of Physicians and Surgeons." Sir Dyce Duckworth (treasurer of the Royal College of Physicians of London) responded for that College. Sir William Mac Cormac (President of the Royal College of Surgeons of England) in his reply said that both Colleges maintained a high standard of professional education, and their examinations would bear comparison with those of any other institution. Sir Thomas Roe, M.P., proposed "The Postmaster-General, the Secretary, and other Executive Officers of the Post Office," to which Sir Robert Hunter and Mr. Edward Yeld replied. In the course of his remarks Sir Thomas Roe said that he was aware that medical officers felt that they had certain responsibilities in connexion with the hygienic condition of the premises occupied by workers whom they attended, and he trusted that it would not be necessary for either Parliament or any other body to interfere with the duties of the members of the association.[1] Sir John Leng, M.P., then proposed the toast of the evening, "The Association of British Postal Medical Officers," to which the Chairman replied.

THE LATE PROFESSOR JOHN HUGHES BENNETT.

ON July 20th a ceremony will take place at the University of Edinburgh which will be of interest to the friends, pupils, and admirers of the late Professor John Hughes Bennett. His daughter, Mrs. Cox, with the view of perpetuating his memory, has caused to be erected an experimental physiological laboratory, with theatre attached and all the accessories needful for modern teaching and research. This, along with a life-sized medallion in bronze of Hughes Bennett, is to be formally handed over to, and accepted by, the university authorities on July 20th. The public ceremony will be an eventful and impressive one, taking place in the McEwan Hall, on which occasion an address will be delivered by Sir J. Burdon Sanderson, Bart., when it is expected that all those interested in the late physician and teacher will attend.

THE DISTRIBUTION OF PLAGUE.

A TELEGRAM received at the Colonial Office on July 4th gives the following statistics of plague in the Cape Peninsula for the week ending June 29th. Fresh cases: European, 1; coloured persons, 3; Malays, 2; natives, 2; East Indians, 0; Chinese, 0; total for the week, 8. Corpses found: European, 1, Malay, 1, total 2. Deaths (including corpses found): European, 1, coloured person, 1; Malay, 1; total, 3.

---

[1] An annotation on the sanitary inspection of post-office buildings was published in THE LANCET of June 29th, 1901, p. 1840.

The total cases and deaths up to June 29th are are as follows: Europeans, 184 cases and 63 deaths; other nationalities (Asiatics and African natives), 538 cases and 284 deaths. The Total up to June 29th, 722 cases and 347 deaths. The plague returns at Port Elizabeth for the week ending June 29th are as follows. Fresh cases: Europeans, 3; coloured person, 1; total, 4. Deaths, 0. The total cases and deaths up to June 29th are as follows: Europeans, 5 cases and 1 death; other nationalities (Asiatics and African natives), 13 cases and 8 deaths. The total cases of plague at all other places up to June 29th are as follows: Europeans, 4; coloured person, 1; natives, 4; total 9. On June 30th four cases of suspicious illness occurred in soldiers at Imvani station, midway between Cathcart and Queenstown in the Eastern Province, where an infected rat was found on June 25th, and a case of plague developed in an employé of the Railway Department on June 27th; otherwise the area of infection remains unchanged. Only nine cases have been reported from the whole of Egypt during the week ending June 30th. Eight of these cases have been reported from Zagazig, among which three deaths have occurred; one death out of hospital has occurred in Alexandria.

THE THAMES IN EFFERVESCENCE.

IT is sometimes said of a person of no particular promise or brilliancy that he will never "set the Thames on fire," or again, a similar expression is used for describing a chimerical and impossible scheme. Thus "You may as well attempt to set the Thames ablaze" is a frequent criticism and very often a perfectly just one. Portions of the Thames, however, have apparently been fired owing to the fact that oil in flames has been seen floating upon its surface, leaking away perhaps from a large oil store-house on fire on its bank or an oil-ship on its waters "well alight." But it is seldom that any part of the great historic waterway is seen to present the appearance of water in a rapid state of ebullition. We have known it as a babbling, but scarcely ever as a bubbling, stream. A bubbling turmoil of this kind, however, may just now be witnessed going on a little to the south of Charing-cross railway bridge. The phenomenon is very singular and calls to mind the natural effervescing springs which are so abundant in Germany, and particularly in the Rhine valley; indeed, the waters of the Rhine itself may at several points be seen to be bubbling violently with carbonic acid gas. It is not so with the Thames in the instance we are describing, for the effervescence is due to the air escaping from a caisson in which men are engaged excavating beneath the bed of the river for the purpose of constructing an electric railway tunnel. The bubbling indicates exactly where the work is proceeding. Sometimes it is near either bank, sometimes in mid-stream, and again in other places, altogether presenting a curious spectacle. It is enough to make the spectator shudder to think what would happen if at any moment the air pressure failed which keeps out the water, for if the pressure were relaxed the water would pour in. And so the sight of a copious stream of huge air-bubbles in the river on this occasion is a welcome one: it means that a superabundance of air exists and that they who labour beneath the bed of the stream may live.

WHAT SHALL WE DRINK?

THE hot days are upon us, when the tendency to thirst is considerably increased and the question may be profitably and appropriately discussed as to how it is best quenched. A perfectly safe answer, we know, would be, not with an alcoholic beverage, but that is only an evasive reply. The reproach is constantly hurled at the extreme temperance advocate that while he forbids wine and all other alcoholic beverages he has no substitute to suggest which can be regarded as possessing anything like the same degree of palatability. What temperance drink, for example, can equal a good cider, a well-brewed beer, not to mention a sound wine. The so-called temperance drinks, if not simply effervescing water are at their best washy concoctions, with a flavour it is true, but one not often pleasing. Then it is the fashion to make up a stock liquor and to charge it artificially with carbonic acid gas, and so instead of the good old-fashioned stone ginger-beer we encounter a perfectly clear decoction containing sometimes ginger and sometimes capsicum. Similarly lemonade is often merely a sugary solution of tartaric or citric acid into which carbonic acid gas is forced, the gas helping in no small measure to keep the composition of the beverage a mystery. Though these may be wholesome enough in their way they are respectively very inferior to brewed ginger-beer or to a lemon squash in which the juice of a fresh lemon is used. Brewed ginger-beer, however, is, strictly speaking, not non-alcoholic, though we doubt if it has ever been recorded that a person got intoxicated on it. In hot weather it is often forgotten that what we drink hot in the winter will afford excellent and wholesome beverages when iced in summer. Thus, iced weak tea and coffee, or even soups, are most refreshing, wholesome, and palatable. Then plain or aerated barley or oatmeal water with a little lemon is an excellent and very salutary beverage. Lime-juice moderately aerated may also be counted as a healthful hot-weather drink. But it is well to bear in mind that even innocent beverages like these can be easily partaken of to a harmful excess. Too much iced-water drinking often proves injurious. To sip rather than to drink should be the guiding principle when thirst is excessive and frequent, and at such times alcohol should be avoided, those beverages rather being chosen which have a cooling effect upon the system. Soda-and-milk is an excellent beverage taken in moderate quantities. Let it be remembered that thirst is a perfectly healthy manifestation and a demand which calls for a healthy answer.

STRUCTURAL IMPROVEMENTS AT THE LONDON HOSPITAL.

THE opening of the new Pathological Institute and the distribution of prizes to the students and the nursing probationers by Sir Henry E. Roscoe, Vice-Chancellor of the University of London, took place on July 10th. The new Pathological Institute has been erected by the House Committee to replace the old post-mortem room and mortuary. The institute consists of two post-mortem rooms with a complete set of laboratories for pathological anatomy, chemistry, and bacteriology in the floor above. Two rooms have been set apart for those who intend to undertake some serious research in pathological anatomy. The Hon. Sidney Holland, speaking on behalf of the Committee of the London Hospital and of the staff, invited Sir Henry Roscoe to declare as open for all time the Pathological Institute, the building of which was an attempt by the hospital authorities to recognise their responsibility to utilise all possible opportunities of helping future generations. Sir Henry Roscoe said that the pathological anatomist, unlike the chemist and physicist, must stand in the closest possible relation to hospital practice. His was the ultimate court of appeal for both physician and surgeon, and in order that his subject might advance he must have access to complete clinical records based on the most advanced knowledge of practical medicine. Moreover, from the nature of the material that occupied his attention the work of the pathological anatomist was intimately bound up with the work of the hospital. In every well-organised laboratory the workers, from the highest to the lowest, formed a family bound together by what might properly be termed the laboratory spirit. The true "laboratory" atmosphere was not that of masters and pupils, but rather that of friends and co-workers; it did not strive after mutual admiration or gain, but it sprang from the knowledge that all who worked in union were united by a recognition of the value of ideas and of honest work. But in order that this true ideal of a laboratory for study and research might be realised mere buildings and equipments were insufficient. There must be at its head a master spirit who could infuse into all the workers his own enthusiasm; a laboratory worked on those lines was the most democratic institution in the world. A man who entered such an atmosphere was judged of by no fictitious attributes of position or power, but solely by his capacity for work and by his love of truth. Lord Lister, in a few words, expressed his approval of the institute and its object. In the course of the afternoon Dr. Stephen Mackenzie, Professor Clifford Allbutt, and Mr. Mansell Moullin also addressed those present. The distribution of prizes took place in the library of the Medical College, the proceedings exciting the greatest enthusiasm, especially on the part of the friends of the successful students and nursing probationers. Miss Kathleen S. Miller won the first prize among the nurses and was warmly congratulated by Sir Henry Roscoe.

THE usual breakfast given by the National Temperance League in connexion with the annual meetings of the British Medical Association will be held on Thursday morning, August 1st, at eight o'clock, in the Parish Room, St. James's-square, Cheltenham. Cards will be sent to any person desirous of attending who will communicate with Mr. John Turner Rae, secretary of the National Temperance League, 34, Paternoster-row, E.C.

H.R.H. PRINCESS LOUISE, DUCHESS OF ARGYLL, performed the opening ceremony at the Kensington Dispensary and Children's Hospital on Monday afternoon last. The addition of a children's ward to the Kensington Dispensary is generally felt in the neighbourhood to be a sound departure.

A GARDEN party was given at Guy's Hospital on July 10th on the occasion of the distribution of medals and prizes to the students by Lord James of Hereford. Mr. Cosmo Bonsor, the treasurer, mentioned that he had received a cheque for £1000 as a thank-offering from Lord Portman.

WE have received Vol. XXXVIII. of the Minutes of the General Medical Council and of its various committees and branch councils from Jan. 1st, 1901, to June 11th, 1901. There are also published with the Minutes 10 appendices comprising various reports and tables.

HER MAJESTY QUEEN ALEXANDRA has graciously intimated her intention of presenting certificates to the eighth and ninth thousand nurses who have joined the Royal National Pension Fund for Nurses, at Marlborough House on Friday next, July 19th.

THE sixtieth annual meeting of the Medico-Psychological Association of Great Britain and Ireland will be held in the medical school of the Queen's College, Cork, Ireland, on Thursday and Friday, July 25th and 26th, under the presidency of Dr. Oscar T. Woods.

THE Public Health Committee of the London County Council brought up at the last meeting of the Council a report containing certain valuable recommendations for restraining the sale of filthy ice-creams. The report was adopted by the Council.

DR. J. J. MARSH has been promoted from Honorary Associate of the Order of the Hospital of St. John of Jerusalem in England to Knight of Grace.

ROYAL MEDICAL BENEVOLENT COLLEGE, EPSOM.

THE twenty-eighth festival dinner of the Royal Medical Benevolent College, Epsom, was held in the Grand Hall of the Hotel Cecil on July 9th, when the Earl of Rosebery, K.G., President of the College, presided. During the course of the evening subscriptions amounting to £4127 were announced by the Treasurer, including 1000 guineas from an anonymous friend and 100 guineas from the Chairman.

After the loyal toasts had been honoured, Lord Rosebery proposed "Success to Epsom College," and in his prefatory remarks described the adjectives connected with the name of the College as being superabundant. As the president of the College he suggested that those adjectives should be left out of the title altogether and the institution called simply Epsom College, with the words "Royal Medical Foundation" as a sub-title. Incidentally, he remarked that he did not see why Epsom College should not rise to the level of Eton. As to the statistics of Epsom College, they were embodied in papers which were circulated among those present. The facts were these, that there was a foundation—he left out the pensioners from his consideration that night, he did not quite know how they became connected with Epsom College—there were 50 foundation scholars in Epsom College for whom exhibitions had to be found from some fund or other, and then there was a difference which had to be met from public funds for those who were sons of medical men and those who were not sons of medical men. That represented a sum of some £6000 a year. The fixed income of the establishment was not one-third of that and considerable reinforcements were required from outside. He took the greatest interest in the school and he had known some of the lads personally as they passed from the school. They could not see finer lads anywhere than they saw in Epsom College. He did not believe that anyone who was conversant with the position which those boys held could refrain from giving it their enthusiastic support. Considering the nature and conditions of the College, how closely it was allied to the medical profession, it was right to ask for a larger support from the public and the profession. From the profession perhaps first, but also from those who had benefited by it: "The devil was sick the devil a saint would be," but when the patient was well he was apt to forget to whom it was that he owed that he was well. They owed much to those who cured them, and in an indirect way by assisting the institution in whose aid they had met that evening, they could show in some measure their gratitude. Did they not all owe a debt which they could not estimate or limit to the medical profession? All professions and all callings had their pain, but of the medical profession alone, perhaps, of all secular professions it might be said that a man on his setting out to do his day's work knew that he could have no object but a beneficent object—to heal and to assuage pain, to combat, and with ultimate ill-success, the chill angel of death. This was a consideration, he thought, which comprehended all humanity in the debt to the medical profession—a profession equal to its duty, whether on the battlefield in South Africa or in the not less arduous task of combating disease at home. They pursued that duty only at the cost of their own lives. It was very easy to fancy that the medical profession was nothing but a brilliant and well-paid one; but when they came to think of the great number of medical graduates turned out every year, and that there were some 30,000 medical men in Great Britain, or perhaps outside of Great Britain just now, they could not but feel that the number of blanks in that profession must be out of all proportion to the number of prizes. The princes and the prizemen were at that dinner, but that was only a small percentage of the great number in the country and of the small practitioners in the towns who were at the beck and call of disease and pain by day and by night, at every hour, in every weather. It was a noble profession, but it was in many cases a profession of forlorn hopes. Those men, when they died, died as truly in the service of their country as many of the men who fell in charge of batteries. They might leave behind them a wife whom they could not maintain, children whom they could not educate. It was for these children that they pleaded that night. There was one medical student—the worst physician, he believed, but the most famous medical student—who in the eighteenth century lay dying not far from there, and as he lay dying—it was an episode he could never forget—they gathered round and asked him, "Is your mind at ease?" The answer, in the words of Lord Macaulay, which had never been obliterated from his mind since he read them, was, "No, it is not." Those were the last recorded words of Oliver Goldsmith. They were the words of thousands who died with that feeling and who belonged to the great profession to which so many there belonged. He asked them to come that night to the assistance of Epsom College with the assurance that everything they gave would be well and worthily expended and that they would have done no better deed in their lives than by assisting to maintain that noble institution

Dr. Holman, the treasurer, in reply to the toast, said that he was quite unable to follow in the eloquent footsteps of Lord Rosebery, but he did not believe that there was a single word uttered by the chairman with which he himself did not completely concur. At the first dinner held after he became an officer of the College he had said that the public did not do their duty to medical men who ministered to their medical needs, and he still held that view. The adjectives attached to the name of the College, he thought, might well be omitted, and he might mention that in the last Act of Parliament which the Council obtained they took the opportunity of deleting the words "medical" and "benevolent" in the clauses of that Act. Epsom College was mainly built by John Propert and members of the medical profession, and Propert could scarcely do less than call a college "medical" which was built by the funds of medical men. With regard to the benevolent part, he had seen in his long life the enormous amount of misery amongst his profession, to relieve which in a very humble way Propert instituted the two classes of pensioners and foundation scholars. It went without saying that in the profession of medicine there must be failures which carried with them misery and suffering. Dr. Holman gave the case of a medical man who, in hastening to the succour of a burnt child, was himself burnt with lightning whilst crossing a wild heath in a storm as a case in which the bread-winner was untimely torn from his family which relied upon him for support, and made the story terribly vivid by detailing personal experiences of his own that might have ended in a like tragic manner. The idea in John Propert's mind, he continued, was not to form a class school but a mixed school—a form of education which he believed was the best. The needs of the school amounted to about £6000 a year, though the numbers varied considerably. Since he had been treasurer some £17,000 or £18,000 had been apportioned to foundation scholarships and pensionerships. To diminish in any way the amount of relief which had hitherto been afforded would result in incalculable misery. If those present and their friends would only make the position of the pensioners and foundation scholars secure the adjectives might go; but the difficulty which he had each year to meet the requirements convinced him that unless people had a *quid pro quo* they would not give the money. That was painful for him to say, but it was true. If the Council were provided with £50,000 they would wipe the whole thing out as regards benevolence altogether; but he did not feel justified in doing so without that security.

The toast of "The Chairman" was proposed by Dr. J L. Propert, a son of the founder of Epsom College, in felicitous terms, his lordship's all-round qualities being insisted upon and reference in particular being made to his sporting successes.

Dr. Holman announced the donation of 1000 guineas from an anonymous friend who had been moved to generosity by Lord Rosebery's speech.

Lord Rosebery said that although the subject of the speech to which he was replying was necessarily a fascinating one to himself he would set limits to his egotism. He was anxious to remove the impression that might be created by Dr. Propert's allusions to his racing successes as to the character of the College over which he presided. He understood that during race meetings the boys were strictly confined to bounds.

A well-arranged evening was brought to a pleasant close by Lord Rosebery's humorous words.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN extraordinary meeting of the Comitia was held on July 4th, Sir W. S. CHURCH, the President, being in the chair.

The PRESIDENT alluded to the cordial reception which was given to the delegates of the College at the recent conference held at Glasgow and announced amidst acclamation that the University of Glasgow had conferred upon him the degree of D.C.L. *honoris causâ.*

A report, dated May 6th, from a special committee of the two Colleges appointed to consider their financial position in relation to the laboratories was received and entered on the minutes, the proposer and seconder being Dr. T. T. WHIPHAM and Dr. W. CAYLEY. In relation to the above a communication from the secretary of the Royal College of Surgeons of England, dated June 21st, was read, reporting further proceedings of the Council on June 20th and forwarding a report of their Finance Committee, dated June 5th, making certain proposals for meeting the working expenses of the laboratories for another year.—Sir DYCE DUCKWORTH moved, and Dr. F. W. PAVY seconded, that thanks be returned to the Royal College of Surgeons for their generous offer.—Sir DYCE DUCKWORTH also moved that for another year, provided that the expenses be strictly limited to £1300, the Royal College of Physicians of London are prepared to bear their share as heretofore in carrying on the work of the laboratories.—Dr. ROSE BRADFORD seconded this motion, which was carried, and also suggested that the expenses of the workers in the laboratories should be defrayed by themselves.—Sir DYCE DUCKWORTH moved, and Dr. PAVY seconded, that a special joint committee of the two Colleges be appointed for carrying on the work of the laboratories.—Dr. NORMAN MOORE proposed, and Dr. W. H. ALLCHIN seconded, that Dr. Rose Bradford's name be added to the committee.—This was carried.

A report, dated June 7th, of the Laboratories Committee was adopted.

The Committee of Management presented a report, dated June 10th.—Dr. NORMAN MOORE proposed, and Dr. S. MACKENZIE seconded, that the proposed regulation that the teaching of the administration of anæsthetics to all candidates for the diplomas of L.R.C.P. and M.R.C.S. be referred back to the committee.—This was carried.

A communication was received from the Dublin Sanitary Association suggesting the transfer of pneumonia from the respiratory to the zymotic class in the "Nomenclature of Diseases," with letters from the Registrar-General for Ireland and the Royal College of Physicians of Ireland.—Dr. J. F. PAYNE moved, and Dr. THEODORE WILLIAMS seconded, that the question be deferred for discussion until the new edition of the "Nomenclature of Diseases" was in preparation when the matter should receive the serious consideration of the College.—This was carried.

The REGISTRAR moved that the amendment of the by-laws, in conformity with the revised regulations of the Conjoint Board, adopted May 9th, 1901, should be re-enacted for the first time.—This was seconded by Dr. NORMAN MOORE and carried.—The result of this resolution is that in future proofs of registration by the General Medical Council will no longer be required of candidates for diplomas granted by the Conjoint Board.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ELECTION OF PRESIDENT.

AT a meeting held on July 11th, Mr. H. G. HOWSE was elected President of the College, and Mr. T. R. JESSOP and Mr. HOWARD MARSH were elected Senior and Junior Vice-Presidents.

ANNUAL MEETING OF FELLOWS.

THE annual meeting of Fellows was called for July 4th, at 5 30 P.M., but no one expected that a quorum (30) would be obtained. The President, Sir WILLIAM MAC CORMAC, Bart., K.C.B., K.C.V.O., and the senior Vice-President, Mr. JOHN LANGTON, with the 16 Fellows who attended, waited for a quarter of an hour in vain.

The abstention of the Fellows is not surprising when it is remembered that there were no agenda and that no meeting had been held since 1897.

Some informal remarks were made suggesting a reduction in the number required for a quorum, but the President did not hold out any hopes of a change.

It is not improbable that the fixed meetings of Fellows will be abandoned, though meetings might be called when necessary.

ADDITIONS TO THE MUSEUM.

On Thursday, July 4th, and the following two days, the Conservator, Professor C. Stewart, F.R.S., exhibited in the Council-room the additions made to the museum during the previous year. When only personal voting for the Council existed this annual exhibition was visited by a large number of Fellows, but now that less than 20 Fellows vote personally the new specimens do not receive the attention that they deserve. There are many interesting pathological specimens, and among them may be specially mentioned a base of a skull which shows a bullet embedded in the body of the sphenoid; the patient survived the injury for many months, but suppuration ultimately occurred at the base of the brain and it proved fatal. There are two examples of excisions of joints which were performed many years ago; one exhibits the portions of bone excised from the elbow by Mr. John Tudor in 1857 and the other shows the excised lower end of the ilium removed by Sir James Grant in Canada in 1864. Mr. Thomas Bryant has presented some curious little elongated calculi removed from the bladder; they have formed on pubic hairs introduced in catheterisation. There is an excellent example of an ovarian pregnancy which was removed by Mr. H. Littlewood from a patient under the care of Mr. G. P. Anning. Mr. F. W. Collingwood has presented a curious native instrument for opening abscesses; it comes from Funafuti, one of the Ellice Islands, and consists of a shark's tooth fastened to a small rod. Mr. J. D. Malcolm has given a very fine dendritic renal calculus and Mr. Bryant a curious double calculus. In the physiological series there are numerous dissections of the muscles and organs of a hedgehog and of a three-toed sloth (Bradypus tridactylus). Three specimens show "Stewart's organs," which are internal branchiæ; the forms shown are Cidaris tribuloides, Diadema saxatile, and Asthenosoma hystrix. The nervous systems of many invertebrates have been most exquisitely dissected and an enlarged model and drawings have been made of the cerebral ganglia of a blackbeetle copied from originals constructed on a new plan by Mr. E. T. Newton who kindly lent them for the purpose. Brains from three gorillas, three orang-outangs, two chimpanzees, and three chiromys obtained from the Zoological Gardens are also exhibited and show the convolutions well. The life-history of a fish (Rhodeus amazus) is illustrated by a series of specimens. A number of Chinese skulls and skeletons have been obtained and are especially of value as the museum was deficient in this branch. Skulls from various Pacific islands are also shown.

ASYLUM REPORTS.

Leicestershire and Rutland Lunatic Asylum (Annual Report for 1900).—The average number of patients resident during the year was 488 and comprised 216 males and 272 females. The admissions during the year amounted to 107—viz., 36 males and 71 females. Of these, 94—viz., 31 males and 63 females—were first admissions. Mr. Rothsay C. Stewart, the medical superintendent, states in his report that 20 female patients are boarded out at the Wells Asylum and 18 at the Beverley Asylum. Of the admissions 23 were known to have had previous attacks of insanity and 34 cases showed some hereditary tendency. The number of epileptics was six and of general paralytics only two, the latter being the lowest number on record for years. During the year 34 patients—viz., 10 males and 24 females—were discharged as recovered, or 6·96 per cent. of the average number resident. The number of deaths during the year amounted to 49—viz., 25 males and 24 females, or 10·04 per cent., as calculated on the same basis. A male patient, admitted in a very exhausted condition, died on the evening of his admission. Amongst the deaths three were due to cerebral softening, two to pneumonia, four to epilepsy, five to general paralysis, six to senile decay, 10 to cardiac disease, and 10 to phthisis and other forms of tuberculosis. There were four accidents involving fractures of bones; three of these were due to accidental falls and one was the result of a violent kick from a patient. All these patients made good recoveries from their injuries. No inquest was held and there was no serious attempt at suicide. Mechanical restraint was not found necessary in a single case. Two male attendants were dismissed for insubordination; with these exceptions the conduct of the staff has been satisfactory. Several of the attendants were still out with their regiments in South Africa and their continued absence was sadly felt. The erection of a new asylum for the two counties had been decided upon and the detailed plans and sections of the buildings, prepared after consulting with, and receiving the consent of, the Commissioners in Lunacy, had been passed. The committee of visitors to the asylum state in their report that the profit derived from the farm and garden amounts to £353 3*s.* 8*d.*, which has to be deducted from the deficiency on maintenance account, leaving a net deficiency for the year of £721 9*s.* 7*d.*, as against a surplus of £23 13*s.* 7*d.* for the previous year. The average weekly cost of maintenance of patients during the year has been 9*s.* 4¾*d.*, as against 8*s.* 9¾*d.* for the previous year. The aggregate expenditure on building repairs for the year has been £1321 13*s.* The Commissioners in Lunacy state in their report that the wards were in good order and the rooms bright and cheerful. The behaviour of the patients was very tranquil and their dress was neat and varied. In the very favourable proportion of 90 per cent. of the deaths post-mortem examinations were made. The post-mortem books and case-books were kept carefully and with intelligence, and were illustrated by excellent photographs of the patients on admission and on discharge.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Rhondda Urban District.—This is a rapidly increasing district, the population of which has risen from 88,351 in 1891 to 129,028 in 1900, and there are now only 19 towns in England and one in Wales with a larger population. The illegitimate births in the Rhondda during 1900 amounted to 24 per 1000 of the total births, and Mr. Herbert Jones remarks that in 1899, the year of the strike, there were fewer illegitimate births than in the previous year or in 1900. Among these illegitimate births the mortality was no less than 308 per 1000 in 1900, and probably even these figures do not convey a correct idea of the magnitude of the evil. In connexion with diphtheria Mr. Jones has shown that he is fully alive to the influence which animals may have in the spread of the disease by issuing a notice to poultry-keepers drawing attention to the symptoms of diphtheria in fowls and to the dangers arising therefrom. With respect to puerperal fever Mr. Jones is to be congratulated upon his vigorous measures. When a case of this disease is notified the nurse in attendance is sent to the hospital, her clothing is passed through the disinfector, and she is given a thorough bath. Special attention is paid to her hands and nails.

Borough of Finsbury (Western Division), Clerkenwell.—Dr. George Newman reports that during the last six years there have been 98 houses in Clerkenwell in each of which more than one case of phthisis has occurred; in some instances there have been several cases. The persistence of infected dust is, Dr. Newman thinks, the cause of the repeated invasion of certain houses, and as a consequence he has persuaded the Public Health Committee to adopt a system of voluntary notification of acute phthisis (cases with mucopurulent discharge or infective sputum from the lungs). The usual payment of 2*s.* 6*d.* is made for each notification and although it is perhaps too early to judge of the results Dr. Newman is so far satisfied that the measure is valuable. It is to be hoped that at the forthcoming Congress on Tuberculosis this subject of the notification of pulmonary tuberculosis will be adequately discussed and that if there is an overwhelming opinion in favour of, or against, such a measure, that it will find expression in a formal resolution.

Belfast Urban District.—The Market Committee of the Belfast Corporation have recently visited certain abattoirs in England and on the Continent, and a report upon the expedition has now been presented. Visits were made to England, France, and Germany, but in the first-named country the attention of the committee appears to have been limited to the City of London Corporation Markets at Smithfield. The report describes the method adopted for dealing with the diseased meat seized at Smithfield. Such meat is steeped in a bath containing picric acid, and when sufficiently stained and coloured it is sold to a contractor who is apparently bound to destroy it. But upon this matter the report, without affording much information, states that the deputation is of opinion that there should be no handling of such meat by *anyone not under the direct supervision and authority of the corporation.* In Paris attention was mainly directed to the abattoir known as "La Villette," and plans, &c., thereof are furnished in the report. The deputation were much struck with the stamping of the meat, and they think that every corporation should adopt similar precautions. They do not, however, recommend that the Paris models should be followed, and they regard the arrangement for pig-slaughtering and singeing as very primitive; there are apparently no pig-singeing furnaces in use, the process adopted being to cover the carcasses with straw which on being ignited singes the pigs. The system used for the destruction of condemned meat is also, in the view of the deputation, very primitive. In the slaughtering of pigs Paris has, the report states, much to learn from Dublin. From Paris the deputation proceeded to Barmen in North Germany which is regarded as one of the best equipped abattoirs in Europe. They regarded the mechanical arrangements in the slaughtering-houses as eminently satisfactory, and they were much struck by Herr Koch's pig-killing apparatus which consists of a bolt which is driven into the skull of the pig and which is drawn back by means of a specially constructed lever. By this method all damage to the skull or soft parts is avoided, as also is the suffering which must attend prolonged slaughter by the knife. In the central Vieh-hof in Berlin the custom is to knock the pigs on the head with the back of an axe, and the result is that a comparative silence prevails in the abattoir. Diseased animals and slaughter-house refuse are destroyed in a double Podewil's apparatus, a full description of which is given in the report. Briefly stated the apparatus aims at utilising all the valuable ingredients of the carcass. The system by which meat of little value is offered for sale in the "Freibank" is of interest. Only meat which has been cooked can be there offered for sale, and hence there can be no likelihood of such meat being sold as thoroughly sound In one of the several appendices to the volume before us an account is given of the municipal knacker yard in Hamburg, and Hartmann's meat steriliser, which is used for rendering unmarketable meat palatable, is described. As a result of these inspections the deputation made the following recommendations. 1. That the stamping of all meat before sale to the public shall be made compulsory. 2. That a veterinary surgeon shall be appointed to take charge of the inspection and stamping both of live animals in the market and of meat before sale. 3. That the condemned animals, carcasses, or meat shall not be removed from the abattoir under any pretence, but shall be retained and destroyed by a qualified staff in the employment of the corporation *only*. 4. That the system adopted for the treatment of condemned meat shall be that known as Podewil's. The cost of the necessary apparatus will not exceed £2000, as the buildings can be erected to suit the apparatus without any exceptional delay and will be capable of dealing with the probable quantity of condemned meat in the city for many years. We have given these recommendations in full because other corporations may be glad to know what Belfast proposes to do.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 33 of the largest English towns 6250 births and 3325 deaths were registered during the week ending July 6th. The annual rate of mortality in these towns, which had been 15 0 and 14·8 per 1000 in the two preceding weeks, rose again to 15·1 per 1000 last week. In London the death-rate was 14·4 per 1000, while it averaged 15·6 in the 32 large provincial towns. The lowest death-rates in these towns were 9·3 in Leicester, 10·7 in Burnley, 11·0 in Swansea, 11·3 in Derby, and 11·6 in Norwich; the highest rates were 19·3 in Gateshead and in Newcastle, 19·6 in Blackburn, 20·2 in Birkenhead, and 21·9 in Liverpool. The 3325 deaths in these towns last week included 431 which were referred to the principal zymotic diseases, against 357 and 399 in the two preceding weeks; of these, 157 resulted from diarrhœal diseases, 95 from measles, 63 from diphtheria, 62 from whooping-cough, 37 from scarlet fever, and 17 from "fever" (principally enteric). No death from any of these diseases was registered last week in Croydon, in Norwich, or in Halifax; in the other towns they caused the lowest death-rates in Swansea, Plymouth, and Preston, and the highest rates in West Ham, Portsmouth, Birkenhead, Liverpool, and Bolton. The greatest mortality from measles occurred in West Ham, Wolverhampton, and Birkenhead; from scarlet fever in Derby and in Blackburn; from whooping-cough in Bradford; and from diarrhœal diseases in Portsmouth, Birkenhead, Liverpool, Bolton, and Leeds. The mortality from "fever" showed no marked excess in any of the large towns The 63 deaths from diphtheria in the 33 towns included 27 in London, seven in Leeds, four in Liverpool, and four in Manchester. No fatal case of small-pox was registered in any of the 33 towns last week; two small-pox patients were admitted into the Metropolitan Asylums hospitals during the week, and six remained under treatment on Saturday, July 6th. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2895, against numbers increasing from 1522 to 2821 on the ten preceding Saturdays; 363 new cases were admitted during the week, against 323, 369, and 408 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had declined from 240 to 141 in the five preceding weeks, rose again last week to 165, but were 46 below the corrected average. The causes of 28, or 0 9 per cent., of the deaths in the 33 towns were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Manchester, Bradford, Leeds, Newcastle, and in 15 other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Sheffield, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·6 and 17·3 per 1000 in the two preceding weeks, rose again to 19·0 per 1000 during the week ending July 6th, and showed an excess of 3·9 per 1000 over the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 6·3 in Perth and 15·1 in Dundee to 20·6 in Glasgow and 24·8 in Leith. The 606 deaths in these towns included 25 which were referred to measles, 25 to whooping-cough, 19 to diarrhœa, seven to scarlet fever, three to diphtheria, one to small-pox, and one to "fever." In all, 81 deaths resulted from these principal zymotic diseases last week, against 97 and 86 in the two preceding weeks. These 81 deaths were equal to an annual rate of 2·5 per 1000, which was 0·5 per 1000 above the zymotic death-rate last week in the 33 large English towns. The fatal cases of measles, which had been 25 in each of the two preceding weeks, were again 25 last week and included 16 in Glasgow, four in Dundee, two in Edinburgh, and two in Leith. The deaths from whooping-cough, which had been 44 and 30 in the two preceding weeks, further declined last week to 25, of which 12 were registered in Glasgow, four in Edinburgh, three in Dundee, three in Leith, and two in Paisley. The fatal cases of diarrhœa, which had been 17, 13, and 24 in the three preceding weeks, declined again to 19 last week, and included seven in Glasgow, four in Dundee, three in Leith, and three in Greenock, The deaths from scarlet fever, which had been eight and two in the two preceding weeks, rose again last week to seven, of which four occurred in Glasgow, where the three deaths from diphtheria and the fatal case of small-pox were also recorded. The deaths referred to diseases of the respiratory organs in these towns, which had been 92 and 95 in the two preceding weeks, were again 95 last week, and showed an excess of 23 over the number in the corresponding period of last year. The causes of 24, or nearly 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been 20·2 and 18·2 per 1000 in the two preceding weeks, rose again to 20·7 during the week ending July 6th. During the past four weeks the death-rate has averaged 19·7 per 1000, the rates during the same period being 14·0 in London and 17·5 in Edinburgh. The 149 deaths of persons belonging to Dublin registered during the week under notice were 18 in excess of the number in the preceding week, and included seven which were referred to the principal zymotic diseases, against 10 and five in the two preceding weeks; of these three resulted from diphtheria, two from whooping-cough, one from "fever," and one from diarrhœa. These seven deaths were equal to an annual rate of 1·0 per 1000, the zymotic death-rate during the same period being 1·8 in London and 1·5 in Edinburgh. The three fatal cases of diphtheria showed an *excess over the number recorded in any recent week.* The deaths from whooping-cough, which had declined from five to two in the four preceding weeks, were again two last week. The 149 deaths in Dublin last week included 21 of children under one year of age and 41 of persons aged upwards of 60 years; the deaths of infants showed a slight decline, while those of elderly persons corresponded with the number in the preceding week. Eleven inquest cases and six deaths from violence were registered; and 58, *or more than one-third, of the deaths* occurred in public institutions. The causes of nine, or more than 6 per cent, *of the deaths in Dublin last week were not certified.*

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE

THE following appointments are notified:—Fleet Surgeon G. Kirker to Haslar Hospital. Staff Surgeons: F. J. Burns to the *Trafalgar* and R W. Anderson to the *Andromache.* Surgeons: E. A. Shaw to the *Apollo;* C. T. Baxter to the *Repulse;* H. V. Wills to the *Niobe;* and P. T. Sutcliffe to the *Duke of Wellington.*

MILITIA MEDICAL STAFF CORPS.

Surgeon-Lieutenant W. Fletcher, D.S.O., to be Surgeon-Captain, and to remain seconded. The undermentioned officers are seconded for service with the Royal Army Medical Corps in South Africa:—Surgeon-Captain A. H. Benson and Surgeon-Lieutenant J. Clerke.

VOLUNTEER CORPS.

Rifle: 24th Middlesex: Surgeon-Captain A. Eddowes resigns his commission.

VOLUNTEER MEDICAL STAFF CORPS.

The Glasgow Companies:—To be Surgeon-Lieutenants: Samuel Macfarlane Sloan, Hugh Wright Thomson, and Archibald Young.

SOUTH AFRICAN WAR NOTES.

The transport *Montfort*, which went ashore on Hampstead Ledge, Newtown, Isle of Wight, on July 5th, and which was subsequently refloated, had on board, returning from South Africa, Civil Surgeons Hodge and Holt.

Major O'Callaghan, Major Hale, D.S.O., and Civil Surgeons A. Strange, H. Y. Taylor, and Boyd are on passage home.

MENTIONED IN DESPATCHES.

The *London Gazette* of July 9th contains a long despatch from Lord Kitchener in which the following officers are mentioned:—

In connexion with the action near Lombert's Bay, Cape Colony, March 1st, 1901, Captain L J. Weatherbe, attached, Royal Army Medical Corps, medical officer, of Paget's Horse, is referred to as having rendered valuable service throughout the day. He took out an ambulance twice under heavy fire. Captain A. H. Sturdee, Victorian Imperial Regiment, medical officer at Middelwater, Cape Colony, on April 22nd, rode half a mile under fire to a donga near the enemy's position in which were some wounded men who needed medical aid. Lieutenant J. H. Patterson (medical officer) in an action near Rhenoster Kop on May 7th proceeded under fire to within 70 yards of the enemy in order to assist wounded men and remained under close fire for over two hours, and, though constantly shot at, continued to attend the wounded and remained behind with them when the patrol withdrew, though he was without red cross brassard.

DEATHS IN THE SERVICES.

Surgeon John Gallagher Corry, R.N., of H.M. cruiser *Niobe*, one of the ships of the Channel Squadron, on July 7th, from phthisis, at the Royal Naval Hospital, Stonehouse. Surgeon Corry, who received his medical education at Queen's College, Galway, and Edinburgh University, graduated M.B, B.Ch, and B A.O. of the Royal University of Ireland in 1897 He entered the Royal Navy as a surgeon on May 23rd, 1898, and was appointed to the *Niobe* on April 23rd last. Surgeon Corry was only a few weeks ago replaced in the *Niobe* by Surgeon P. T. Sutcliffe in order that he might have the benefit of hospital treatment. The deceased was very popular amongst his brother officers and much regret is felt at his early death.

Fleet Surgeon Matthew Fletcher Ryan, R.N., retired, died suddenly at the Junior Army and Navy Club on July 5th from heart disease He entered the service in 1868 and retired with the rank of Fleet Surgeon in 1898.

THE NEW NAVAL HOSPITAL AT KEYHAM.

Rapid progress in being made with the naval hospital attached to the Royal Naval Barracks at Keyham. The new building which, it is hoped, will be ready for occupation by January next, will provide accommodation for 40 patients. The hospital, which will be used solely by the medical staff *at the general depôt, will greatly relieve the heavy demands* made on the resources of the Royal Naval Hospital at Stonehouse.

Correspondence.

"Audi alteram partem."

VIRCHOW'S EIGHTIETH BIRTHDAY.

To the Editors of THE LANCET.

SIRS,—I learn from Professor Waldeyer that Virchow's eightieth birthday will be celebrated in Berlin on Saturday, Oct. 12th, when he will personally receive delegates with congratulatory addresses from various scientific bodies, foreign as well as German.

A preliminary notice of the intended celebration was given by Sir William Turner at the meeting of the General Medical Council last November to the representatives of the universities and medical corporations on that body; and if such of them as desire to be represented on the occasion will kindly send to me as soon as convenient the names of the delegates appointed I will communicate them to Professor Waldeyer who is the president of the executive committee. Further particulars as to arrangements will be furnished later. The insertion of this letter in your columns would oblige

Yours truly,
LISTER.

12, Park-crescent, Portland-place, W., July 6th, 1901.

"UNBOILED v. BOILED MILK."

To the Editors of THE LANCET.

SIRS,—The kind and forcible criticisms which my letter has evoked and the substantial agreement with my views which other correspondents express, equally make it evident that in this question I have hit the nail on the head. From the interest shown in the subject it is clear, too, that the time has arrived for the profession to exert its influence in practice.

That epidemics arise from impure milk there can be no doubt, and that infants and children suffer from tainted and fermented milk is likewise certain. But this latter difficulty should be met by the sterilisation or boiling of the milk for *infants during the few hot days* we experience in this country, when milk is likely to become sour. It is the habitual use of sterilised and boiled milk, and *all that series of prepared*

REBOUND

milk which are similarly treated, which is answerable for such disastrous consequences.

When a man of the calibre of Dr. F. J. Smith, of great experience at the London Hospital in connexion with boiled milk in the East-end of London concurs with me who reside in *the country* it is not unreasonable to think that the arguments and assertions of my generous critics are refuted by this conjoint experience and the conclusion based thereon. I would only point out that the remedy for poisoned milk is not the increase of the evil by boiling, but the provision that the milk is issued safely to the public by a thorough organisation of the inspection of dairies and dairy cows with adequate penalties for failure. True, the dairyman is punished for diminishing the nutritive value of milk by adding water when a rare conviction can be secured; but this is insufficient. Ignorance, criminal carelessness, and fraud are practised in the sale of milk more extensively than in any other article of food. The trade is one of the most lucrative, as shown by the position of even small traders, so that it can well afford the compulsion of more intelligence, greater care, and stricter honesty. When the profound influence of purity in this universal article of food upon the physical vigour, and consequently the mental power, of the nation is considered the subject assumes an infinitely more serious aspect and demands the united and persistent action of the profession in securing legislative measures of a thoroughly searching and vigorous character. I am, Sirs, yours faithfully,

Rugby, July 8th, 1901. CLEMENT DUKES.

To the Editors of THE LANCET.

SIRS,—I am glad to see that such an able authority as Dr. Clement Dukes has taken up this question and that his experience leads him to advocate the use of unboiled milk. For a considerable time I have employed fresh unboiled milk in the feeding of infants. I was led to adopt this line of treatment because of two successive cases, one of scurvy and another of severe malnutrition, which occurred in my practice as the result of continuous feeding on boiled milk. Other cases I can now recall which I am satisfied were due to the regular employment of boiled milk. But although I have been ten years in practice I can recall no case of tuberculosis amongst infants and the larger proportion of my patients must have been brought up on unboiled milk. The fact is, that in my experience tuberculous disease of the glands and peritoneum in children is more frequent after the child has passed the purely milk stage.

The question arises, Why does boiled milk cause scurvy and other diseases of malnutrition? Dr. Corlette some 12 months ago gave it as his opinion (based on experimental and other evidence) that scurvy in infants was due to loss of citric acid in the boiled milk. He said that the disease could be cured by giving fresh milk, or lemon or orange juice, all of which contained citric acid. But scurvy can be cured by fresh vegetables which contain no trace of citric acid or allied body. The fact is, that boiling alters the whole composition and constitution of milk. The same may be said of pasteurising. Either process drives off the gases, the flavouring principle and the fats are changed and rendered less ready of digestion, the proteids are altered, and the salts in general are altered and become deposited in great part either on the bottom or on the sides of the vessel. In short, the whole nutritional value of the milk is changed. Instead of boiling the milk we should insist upon having it pure, and if we cannot have it pure then let us behead either the medical officer of health or the cowkeeper, for one or the other is guilty. I am, Sirs, yours faithfully,

Leeds, July 4th, 1901. GORDON SHARP.

To the Editors of THE LANCET.

SIRS,—There are three questions regarding milk about which differences of opinion exist and require definite settlement: 1. Is the nutritious quality of milk altered by boiling? 2. Is the tubercle bacillus, together with other disease germs, killed by boiling? 3. Is the milk of tuberculous cows a common cause of tuberculosis? In reply to the first question Dr. Corlette, connected with the department of pathological chemistry, University College, London, says: "Citric acid is present in fresh milk, notably diminished in sterilised, but less so in pasteurised milk. It is abundant in lime-juice. With this it is found that infantile scurvy does not occur under a sufficiency of fresh milk, does occur with sterilised, and does not, or very rarely so, with pasteurised milk." Dr. Kerr, late examiner in chemistry and medical jurisprudence, Aberdeen University, says: "The *chemical* result of boiling is to kill all the living cells and coagulate all the albuminoid constituents. Milk after boiling is thicker than it was before. The *physiological* results are that all the constituents of the milk must be digested before it can be absorbed into the system." Therefore there is a distinct loss of utility in the milk, because the living cells of fresh milk do not enter into the circulation direct as living protoplasm and build up the tissues direct as they would do in unboiled milk. In practice it will have been noticed by most medical practitioners that there is a very appreciable lowered vitality in infants fed on boiled milk.

The next point for consideration is, Are disease germs which may chance to be present in milk destroyed by boiling? Dr. Fayel stated some time ago in the *L'Année Médicale de Caen* that he did not believe the tubercle bacillus was destroyed by boiling, since experiments at the Physiological Institute showed that the degree of ebullition of milk never exceeds 100° C., whereas the tubercle bacillus is only killed at a temperature of from 110° C. to 115° C. Mr. Watson Cheyne, of King's College, said: The temperature necessary to kill bacteria depends upon whether they are in the adult or spore condition. In the spore condition in milk it would need somewhat prolonged exposure to a boiling temperature in a warm bath to destroy them, but when I worked with these things I found the only successful way was to boil for 10 or 15 minutes, on three successive days, thus giving the spores a chance of sprouting in the interval and catching them as adults. The last point is to whether the raw milk of tuberculous cows commonly produces tubercle in the human being by its regular use. Well, the veterinary department of the Board of Agriculture put forward the statement some time ago that the results of their experiments with the unboiled milk of tuberculous cows were entirely negative, and Dr. Vivian Poore's evidence on this point is certainly very striking, as is also that of Dr. Clement Dukes. The evidence on the other side will be awaited with interest, but it must be very strong to be convincing.—I am, Sirs, yours faithfully,

Bexhill-on-Sea, July 9th, 1901. F. P. ATKINSON.

To the Editors of THE LANCET.

SIRS,—The main objection which Dr. Dukes and others raise to the boiling or sterilising of milk appears to be that its nutritive value is greatly impaired by the process. Unfortunately, however, in three letters strongly condemning the practice no direct evidence of this diminished nutritive power is given, and the indirect evidence is most meagre and indefinite and only relates to boiled milk. In spite of this lack of direct evidence there appears to be a general consensus of opinion that milk may be so altered in the process of sterilisation as to lead to rickets or infantile scurvy in the consumer. If this is so it is important to learn something of the nature of the change and whether it is an essential part of the process of sterilisation or merely an accident which may be avoided. The chief dietetic cause of rickets is undoubtedly deficiency of fat, that of infantile scurvy some remote and little understood change in the food. While it is impossible to trace the effect of boiling on the antiscorbutic constituent of milk it is not difficult to see the effect produced on the fat and to suggest one connecting link between boiled milk and rickets. When milk is boiled in an open vessel the cream rises pretty rapidly and a large proportion of it becomes entangled in the skin which forms on the surface, thus being lost to the consumer. In addition to this the minute globules of fat coalesce into larger masses and are rendered less easy of absorption. These plain physical facts go far to explain the loss of nutritive power in boiled milk, but they form no essential part of the process of sterilisation. If milk is heated rapidly in covered vessels to a temperature just short of boiling point, the vessels then sealed and cooled rapidly from below upwards, this separation of the fat can be largely prevented and the milk retains much nutritive power that would otherwise be lost. At the same time, all the more dangerous organisms that are known to be commonly present in milk are destroyed. This process is simple and forms a reasonable compromise between boiling or complete sterilisation on the one hand and the use of raw milk on the other.

I have only seen one case of rickets which I could attribute to the use of boiled milk. I questioned the mother as to her methods and was informed that the milk was boiled in an open pan, the skin which formed on the surface being taken off and thrown away As by this means the child was being fed on skimmed milk the onset of rickets was not surprising Is it not possible that many of the evils attributed to sterilised milk are really due to this unnecessary separation and rejection of the fat?

I am, Sirs, yours faithfully,

Prescot, July 9th, 1891 LEONARD YOUATT, M B Vict

THE CASE OF THE LATE MR. R. B. ANDERSON.

To the Editors of THE LANCET

SIRS,—We shall feel much obliged if you will give us your powerful aid in bringing before the medical profession and the public the following facts in connexion with the late Mr R. B Anderson, F.R C.S Eng, whose widow and two orphan sons are now living in Tobago and are in the most straitened circumstances A strong representative committee—with power to add to their number—has been formed with the view of appealing for assistance to those members of the medical profession and of the public who knew and sympathised with the hard case of Mr Anderson which aroused more interest and sympathy than any other *professional case of recent years* and raised a most vital point in medical ethics Shortly, the history of this case is that after being for some time in attendance on a private patient in Tobago Mr Anderson refused to continue his attendance owing to her husband's personal rudeness to himself On this an action was brought against him by the patient and her husband, and Chief Justice Gorrie (of Trinidad and Tobago) gave damages against Mr Anderson for neglect in retiring from the case, although the attendance of another medical man had been immediately secured and no injury to the patient was proved. Mr Anderson resisted this judgment; excessive bail was demanded from him, and in default he was imprisoned and in the end ruined by this and other illegal acts of judicial oppression Mr Anderson then came to England, a committee was formed to assist him in carrying the West Indian judgments in appeal to the Privy Council, and Mr Anderson in person brought an action before the late Lord Chief Justice Coleridge in the Queen's Bench for the recovery *of damages against the colonial judges An English special* jury gave a general verdict in his favour with £500 against one of the judges (Chief Justice Gorrie having died just prior to the trial), but Lord Coleridge gave judgment for the judge against Mr Anderson and the verdict in his favour on the ground that no civil action for damages would lie against judges for acts done in their judicial capacity This judgment was confirmed on appeal, and from want of funds a further appeal to the House of Lords and the proposed colonial appeal to the Privy Council were rendered impossible Finding his legal remedies unsuccessful, owing to the insufficient support which he received from the corporations and associations of the profession, Mr Anderson began an active campaign of medical reform, by which means alone he saw any hope of proving the justice of his case and securing for the future the rights of the profession which were involved in his case, together with others which, in his opinion, required protection His life terminated suddenly from heart disease, under pathetic circumstances, on Nov 8th last, and our committee feel that many in the profession, as well as others, will be ready—whether or not they were in agreement with Mr Anderson's views and methods—to respond to this appeal on behalf of his necessitous family Donations "for the Late R B Anderson Fund" sent and made payable to the Manager, Union Bank of London, Chancery-lane, London, will be duly acknowledged and the amount subscribed will be dealt with as our committee, by resolution, may decide.

We are, Sirs, yours faithfully,

STAMFORD,
Chairman
TIMOTHY HOLMES,
Honorary Secretary

THE CIVIL SURGEON AT THE WAR.

To the Editors of THE LANCET.

SIRS,—I received a letter from my husband yesterday from South Africa in which he asked me to ventilate in your columns certain grievances under which he, in common with all other civil surgeons, is labouring When they sign a contract with the War Office which binds them to a year's service they are given a cheque for one month's salary and 90 days' field pay. As no allowance is made for uniform or camp outfit the whole of this money is swallowed up in providing these necessaries and the civil surgeon starts South African life practically in debt He ranks as a captain All other captains, nursing sisters, civilian veterinary surgeons, and officers of the line are given a colonial allowance The civil surgeon has only a field allowance of 3*s* 6*d* a day, 1*s* 6*d* for his servant, and nothing more, whereas the above mentioned officers receive the same field allowance, together with an extra 3*s*. per day as colonial allowance My husband has to pay 4*s* per day for mess, so that it will be easily seen that his field allowance does not cover his expenses. When one reflects that beer is 1*s* 3*d* a bottle and eggs 9*s* 6*d* a dozen not much margin is allowed for luxury The wear-and-tear to clothes, too, is very great, and the civil surgeon who starts on "trek" with a field allowance of 3*s* 6*d* a day is likely to be a good deal out of pocket Although my husband took up his duties at Aldershot on April 6th up to the date of writing he had not received one penny of his pay.

I am, Sirs, yours faithfully,

July 9th, 1901 E L F.

BRITISH MEDICAL MEN AND GERMAN WATERING-PLACES.

(FROM A CORRESPONDENT)

BAD NAUHEIM has been visited within this last week by an association from England of about 32 medical men and one lady doctor who have gone the round of nearly all the German watering-places in order to be in a position to speak positively as to the properties of the various baths and waters after a personal examination on the spot

They have been most handsomely entertained by the local medical men and the various district authorities in each centre Many of them left England with a certain amount of scepticism and misgiving as to what had been said in the medical and lay press as to the various reputed properties of certain waters I cannot help thinking that if visits of this kind were more frequently undertaken by medical men in the pursuit of science and knowledge it would tend to open our minds to a correct appreciation of the benefits to be derived from a visit to districts where Providence has placed within our reach waters containing certain salts and minerals which undoubtedly are of benefit to the human race when properly used under the direction and supervision of local medical men who have devoted themselves to the study of certain diseases and of the proper application of the waters externally in the form of baths and also internally in the form of table waters, and of waters taken in the early morning at the springs The early rising so much *practised at all watering-places*, with a certain amount of exercise and attention to eating, drinking, and smoking all tend to improvement in suitable cases.

The medical visitors arrived in Bad Nauheim on Wednesday evening, June 26th On Thursday morning Dr Schott met them at his private house and again at the baths in the forenoon He explained to them the properties of the various springs and waters, the cases for which they proved so remarkably successful, and his reasons for believing in their virtues On the same evening I had the pleasure of being one of those who met by invitation of Dr Schott at his house He gave us a very excellent address founded on his ripe experience of the effects of the sprudel waters of Nauheim on the motor and sensory nerves He also laid great stress on the injurious effects of excess in cycling, football, running, rowing, and the abuse of tobacco—in fact, the serious effects on the heart from any serious and violent strain. The progressive and insidious character of the heart trouble when, without any previous ill-effects being observed, a sudden collapse takes place was insisted upon by him

He explained the uses and mode of application of what is now known as the Schott method of exercises. He deprecated all mechanical aids as not being subject to proper supervision by a professional assistant. He then divided the party into groups of six in as many rooms where his own medical assistant and five or six other qualified masseurs gave practical demonstrations of the Schott method of exercises on the medical men present. The pulse was carefully noted by some of the other medical men and a comparison was drawn between the rate and the volume of the pulse when the exercise was properly and judiciously applied as against that when it was violently and jerkingly done. The medical visitors were invited to ask him any question in regard to anything and everything they had seen in the place. Many of them availed themselves of the opportunity. They expressed themselves as being very pleased with the demonstrations and grateful to Dr. Schott for giving up so much (about four hours) of his valuable time to explain and to instruct them in the chief uses and benefits to be derived from a visit to Bad Nauheim. I can only say for myself that after a sojourn here of about a month I have seen a great many cases of heart disease treated by Dr. Schott with most marked benefit and relief.

July 1st.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Decline of the Plague.—Increase of Famine.—Precautions with regard to Drinking-water.

A GREAT drop took place in the plague mortality last week, only 829 deaths being recorded for the whole of India. The Bombay Presidency had 402 deaths, the Punjab 146, Bombay city 100, and Bengal 50. The outbreak has declined at Karachi, but more cases have occurred at Poona. The number of cases continues about the same in Calcutta.

The latest famine returns show an increase of 17,200 in British districts in Bombay and of 9500 in Bombay native States. There are now 483,870 persons on the lists, of whom 106,500 are receiving gratuitous relief.

It has been decided to roof in all drinking-water reservoirs connected with cantonments in India, and the work is to be taken in hand as funds become available.

June 15th.

The Plague Epidemic.—Medical Allowances and Fees.—The Training of Sanitary Inspectors.—The Malaria Scientific Commission.—The St. John Ambulance Association.—The Jails of Bengal.

THE downward course of the plague epidemic throughout India has suddenly stopped. During the past week 847 deaths have been recorded, as against 829 for the previous week, and small increases are reported in the Bombay Presidency, Calcutta, and the Punjab. On the other hand, Bombay city, Karachi, the Bengal districts, and Kashmir show a slight diminution. At Belgaum alone has there been any marked change and here there is recorded a rise from 153 to 176. During the corresponding week of last year there were only 319 deaths from plague throughout the whole of India. The health of Calcutta has markedly improved during the past few weeks and were it not for plague the death-rate would be below the average. The death-rate in Bombay city has also considerably improved.

A diminution of allowances to medical officers seems to be the order of the day. It is notified in the *Gazette of India* that the usual report to the Government is dispensed with in the case of medical officers attending native chiefs and gentry when the fee charged does not exceed 50 rupees a visit or 1000 rupees in the aggregate during the year. It is difficult to understand wh[illegible] [illegible]lation of this sort is imposed on the medical service. [illegible] opinion[illegible] certainly tend to make the Indian Medical Service unp[illegible]ous. Again, the Government of Bombay has sanctioned conveyance allowance of 25 rupees per mensem to military and medical officers specially deputed on plague duty, who are in consequence of such employment compelled to make use of a carriage or horse. This amount is usually granted to quite subordinate officers and would only cover half the expenses necessarily incurred. In the early days of plague duty in the Bombay Presidency 50 rupees a month were granted. Surely there is no reason why this allowance should be now made so small.

The training of sanitary inspectors is at last being taken up. Following the lead of Madras the Bombay Government has appointed a committee to prepare a scheme for carrying out a course of practical study in sanitary science. It will be adapted for students who have passed through the medical and engineering colleges.

The delegates of the Malaria Committee of the Royal Society, Dr. J. W. W. Stephens and Dr. S. R. Christophers, are about to investigate cases of blackwater fever which have been reported from the Duars and Sylhet and other malarious places in India. Dr. Christophers will first go to Mian Mir and Amritsar and work in coöperation with the medical officers of military cantonments against malaria. On the return of Captain James from China this scientific Commission will go to Darjeeling, Terai, and the Duars to investigate blackwater fever.

A native who was bitten by a jackal was sent to the Pasteur Institute at Kasauli. He went through the treatment and was discharged well. A portion of the brain of the jackal preserved in glycerine was sent to Kasauli and experiments were made with this on a rabbit with the result that the rabbit died from typical rabies.

The organisation of the work of the St. John Ambulance Association seems to be proceeding very rapidly. An influential committee has been formed in Bombay and a large staff of lecturers has been appointed. Steps will be immediately taken for the formation of several classes. At Simla also the work of the Association is being actively pushed. In Calcutta several classes have been already held and many others are in course of formation. The work in the Mofussil is also being organised and classes are to be formed at the principal stations.

A resolution of the Bengal Government on the report on the administration of the jail department for the year 1900 has just been issued. There has been a great increase in, and especially of short term, prisoners. The average convict population (excluding the sick) was 17,332. The mortality throughout the province was unusually high—the death-rate having risen from 23·4 to 40·3 per 1000. The report is silent as to the causes of this rise. The year was an unhealthy one and the higher price of grain is thought to have driven many of the poor and half starved to crime. The death-rate among prisoners less than six months in jail was 54·7 per 1000. Cholera again was prevalent and added to the mortality and was especially common amongst the "under-trial" prisoners. This disease alone caused a death-rate of 4·2 per 1000. Deaths from phthisis and pneumonia still continue to form a large proportion. Overcrowding and defective ventilation owing to the unusual number of convicts, which kept most of the jails filled almost to the limit of their capacity, are put down as the chief contributory causes. The recall to military duty of many officers left the charge to military assistant surgeons and native assistant surgeons. The jail report is conspicuous for its shortness and cardinal points in the administration of the department are noted to have escaped mention by the reporter.

June 20th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Liverpool University Question.

AT its meeting on July 3rd the City Council enthusiastically endorsed the movement of the governors of University College in favour of creating a University for Liverpool, some members strongly advising monetary support from the council should the project become an accomplished fact. Mr. Alderman Burgess proposed the following motion:—

> That this council has observed with much satisfaction the growth and progress of University College, and in view of the fact that the college authorities are taking steps to procure the establishment of a separate university for Liverpool, records its opinion that it is desirable in the interests of higher education in the city that such a university should be founded.

The motion had derived additional interest from the attitude of the court of governors of the Victoria University, the meeting of which was held at Owens College, Manchester, on June 29th, and which was adverse to the aspirations of the governors of University College. Be that as it may, Liverpool has made up its mind to have a university of its own, and opponents in other places must only bow gracefully to the inevitable. Alderman Burgess, in a sympathetic speech in support of his motion, said that there were some things so obviously for the public advantage that they did not admit of dispute, and a university for Liverpool was one of them. Anything which made the acquisition of knowledge more available and more attractive concerned the public University College, when founded in 1881, began with six professors, five lecturers, and 45 students In 1900 it had 25 professors, 40 lecturers, 490 science and art students, and 166 medical stude[illegible] and classes [illegible] nearly £500,0[illegible] College declai[illegible] doing until it stood alone, and when the council of the college was unanimous in its opin[illegible] be established in Liverpool, the [illegible] the institution to attain a position [illegible] distinction. Those associated with Victoria University who opposed the scheme knew nothing of the conditions and requirements of Liverpool. It was evident that the appointment by the court of Victoria University of a committee of 15, among whom were only four representatives of Liverpool, was not a satisfactory way of dealing with the question. A university in Liverpool would permeate the whole educational system of the city, and as Liverpool had a world wide celebrity as a centre of commerce, why should it not be destined to have a world-wide influence as a centre of intellectual activity? The motion was warmly supported by Sir William Forwood, who said that during his visits to the United States he had been much impressed by the great work done there by the 60 universities in educating the masses It was also pointed out that the success of the Scottish educational system and of the people themselves was largely due to the influence of their four universities The motion was carried unanimously Public opinion in Liverpool is practically unanimous in favour of the project which has been in the air for a considerable time.

The Birkenhead Guardians and the Lady Doctor Question

The Birkenhead guardians have again found a difficulty in procuring a male resident medical officer for the Birkenhead workhouse In THE LANCET of June 29th, p 1865, the refusal of the guardians to sanction the appointment of a qualified lady to the post was commented upon It now appears that the board's second advertisement inviting applications for the post from male candidates received no response from individuals of that sex It thus became a matter of "Hobson's [illegible] who had [illegible] as there [illegible] of £120

July 9th

WALES AND WESTERN COUNTIES

(FROM OUR OWN CORRESPONDENTS)

Conviction under the Infectious Diseases (Notification) Act

AT the Merthyr Police court an assistant to a colliery surgeon at Treharris was recently fined 10*s* and ordered to pay the costs of the proceedings for neglecting to notify a case of scarlet fever which had occurred among his patients The defence raised was that the case was a doubtful one and might have been German measles although it was admitted that the parents of the patient were told that she was suffering from scarlet fever in order that extra care might be taken In the course of the hearing before the stipendiary magistrate it was stated that it was the custom in the Merthyr district for the principal and not his assistant to notify all cases, whether he had seen them or not. This is by no means the universal practice in other colliery districts of South Wales, where the assistants very commonly notify cases which they see and, as a matter of course, receive the fees Scarlet fever has been very prevalent in Merthyr during the whole year, in the first quarter there were 149 cases of the disease notified and in April and May there were 212 cases The population of Merthyr at the last census was 69,227—an increase of about 10,000 upon the previous census

Death under Chloroform

On June 30th a death occurred at Barry during the administration of chloroform. A woman, aged 32 years, had miscarried during the previous week, and with the intention of clearing out the contents of the uterus the medical attendant, with the assistance of a colleague, placed the patient under chloroform It was noticed that the breathing stopped in less than three minutes from the commencement of inhalation

Swansea Poor-Law Appointments

Upon the rearrangement of the medical appointments of the Swansea Union it was decided to appoint a medical officer for No 1 district and for the workhouse at a salary of £450 per annum, and an assistant medical officer for the workhouse at a salary of £200 yearly For the former post there were 24 candidates, and Dr R J Lloyd Edwards has been appointed For the position of assistant medical officer only two applications were received and these were subsequently withdrawn The board of guardians has therefore decided again to advertise the post

Society of Medical Officers of Health

At the meeting of the West of England and South Wales Branch of the Incorporated Society of Medical Officers of Health, held at Taunton on July 4th, Dr H J Alford called attention to certain defects in the Infectious Diseases (Notification) Act, especially as regards doubtful diagnosis and dual notification, and insisted upon the necessity for providing a sufficient number of observation wards in connexion with isolation hospitals Mr J C Heaven of Bristol was elected president of the branch for the ensuing year

Death of Mr R. C Hunter, L R C P Edin, M R.C S. Eng, of Pontypridd

By the death, on July 3rd, of Mr Robert Charles Hunter the county of Glamorgan loses one of its most prominent medical practitioners. Mr Hunter began to practise in Pontypridd early in the "sixties" when the colliery districts were being opened out. For many years he was surgeon to the Taff Vale Railway Company, and upon the passing of the Workmen's Compensation Act, 1897, he was appointed medical referee under the Act, a position which he retained only for a short time

The Housing of Quarrymen

Dr Le Neve Foster, His Majesty's Principal Inspector of Mines, in his reports for the years 1886, 1888, and 1892 drew attention to the unsatisfactory manner in which the quarrymen of some of the Welsh slate mines were housed and he returns to the subject in his report for the year 1900 The men frequently sleep two in a bed upon straw and are covered with a single sheet which is rarely washed, and they eat, drink, and sleep in the same room The manner in which the Italians who work in the Frongoch mines near Aberystwith are treated by their employers is very different, for each man has a separate bed and sleeps upon a woollen mattress on a spring mattress and the employers pay for the frequent washing of the bed-clothing A separate room is also provided in which the men can take their meals At the waterworks undertaking of the Birmingham Corporation the navvies sleep in separate cubicles, of which there are eight in one ward, and there are three wards in each hut In connexion with the construction of several waterworks in Glamorgan the discarded broad gauge carriages of the Great Western Railway Company have been converted into workmen's huts When these are connected by corrugated iron roofing they adapt themselves very readily to the purpose of temporary lodging houses the compartments of the coaches becoming cubicles and the roofed-in spaces being used as kitchens and meal rooms

Brentry Homes for Inebriates

At the meeting of the Somerset County Council held on July 1st it was reported that the authorities at the Brentry Homes found great difficulty arising from the character of the male patients sent to them Out of 22 male patients at the home on June 17th two had absconded after first attempting a revolt five were under orders to be sent to Cardiff Gaol, with the sanction of the Home Secretary, and several more were being removed, so that only six patients would remain A meeting of the committee of the Homes was held on July 24th and the conclusion was arrived at that it was impossible for the Brentry homes to be carried on if they were obliged to admit male cases The men were very riotous and some had served terms of penal servitude The committee had written to the Home Secretary to see if some means could be adopted of meeting the difficulty by a grant of money or by some special warders being sent if the homes were required to continue to receive male patients

University College of South Wales and Monmouthshire

At a largely attended meeting of the court of governors of the University College of South Wales and Monmouthshire, held on July 1st, it was decided that Lord Tredegar and Mr. Alfred Thomas should represent the court and Senate and should approach Dr. Isambard Owen with a view to his acceptance of the principalship of the College.

July 8th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Notification of Tuberculosis.

AT a quarterly meeting of the Corporation of Dublin held on July 1st Mr. Bergin proposed that a report of the Public Health Committee should be adopted recommending, on the strength of Sir Charles Cameron's opinion, that tuberculosis should be added to the schedule of notifiable diseases as a tentative measure for 12 months. Sir Thomas Pile, in seconding the adoption of the report, said that the disease in question was one of the greatest scourges of the city and did far more injury than typhoid fever. After a long discussion the report was rejected by 40 votes to 19.

Catholic University Medical School.

At a meeting of the governing body held on July 8th a report from the medical faculty was read in which the great increase in the number of students which has taken place recently was dwelt upon. This increase—nearly 30 per cent.—places the medical school in the premier position as regards the number of its pupils among the schools of Ireland.

Health of Dublin.

At a meeting of the governors of the Cork-street Fever Hospital and Home of Recovery held on July 4th the registrar reported that the admissions during the month of June were numerous on account of the continued prevalence of scarlet fever, diphtheria, and pneumonia, while the number of enteric fever cases had decreased. The report of the Public Health Committee for the last week of June shows that a vast change for the better has recently taken place, the average death-rate for the month being only 19·5, as compared with figures between 30 and 40 registered during the winter and spring.

The Heat-wave in Belfast.

During the past 10 days an extraordinary heat-wave has been experienced in Belfast. Thursday, July 4th, was the hottest day, the temperature registering 77° F. in the commercial news-room of the city, this being the highest temperature ever recorded in that public room which has a northern aspect. The peculiarity of the weather is the very great heat at night. Of course, this weather is admirable for the country districts where hay-making and other farming occupations are in full swing.

The Health of the City of Belfast during 1900.

Dr. H. Whitaker, medical superintendent of the city of Belfast, has just issued his annual report for the year 1900. There were 7642 deaths from all causes during 1900, the number being less than in either of the preceding years. Of these 2899 were attributed to chest affections and 737 to zymotic diseases—making a total of 3636, or nearly one half of those registered as having died from all causes. As to the causes of death, of the other 4006 the medical officer of health regrets he has not the information to give. He knows nothing of where any deaths take place except from the Registrar-General's returns, which merely state that so many deaths occur in a certain district. Of the 2899 deaths reported from chest affections 1784 were attributed to diseases of the respiratory organs and 1115 to phthisis. Of the zymotic diseases, typhoid fever has occasioned the greatest mortality. 1777 cases were reported during the year and there were 261 deaths. Diarrhœa caused 241 deaths, whooping-cough 115, diphtheria 54, and measles 42. The deaths of infants under one year old per 1000 births were 152. The death-rate in Belfast from all causes was 21·3, that from zymotic disease being 2·1, and from chest affections 8·1, while the birth-rate was 31·2. The great blots on the health of Belfast are the terrible mortality from phthisis and the continued prevalence of typhoid fever. No attempt has yet been made to grapple with these two problems, as has been done in other cities and towns.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Law as to the Practice of Pharmacy.

IN 1899 a Bill dealing with the practice of pharmacy was introduced into the Chamber of Deputies by M. Astier, M. Morel, M. Bernard, and M. Bachimond. The committee upon trade and industries is at present occupied in hearing evidence upon this Bill given by the various persons interested. Moreover, an opposition Bill has been introduced, backed by the superior schools of pharmacy, which proposes to introduce some important modifications. The chief one must be considered as the beginning of a campaign undertaken against proprietary medicines, a campaign originally initiated by a majority of retail pharmacists who some time back gave out that they were going to fight against proprietary articles. The law as at present declares that if a proprietary preparation is not in the Codex the label must contain the names of the active substances which go to make up the medicine. The Bill introduced by the schools of pharmacy demands that the label shall bear the name of every substance, active or not, which goes to make up the medicine. If this Bill is passed it will have a disastrous effect upon the manufacture of pharmaceutical specialities, for the essence of these consists in their having a particular mode of preparation, for the purpose of either making the medicine more agreeable to take or of bringing about some intricate chemical action, a matter which is jealously guarded by the maker, for in this way his preparation is better protected than by any amount of trade-marks. If the method of preparation has to be made public in every detail imitations of the best-known and most appreciated products will become common, and that industry which is so flourishing in France of making pharmaceutical specialities will be markedly affected. It is obvious that the pharmacists who are engineering this project have foreseen this result, for the prosperous condition of the wholesale manufacturers excites their jealousy, more especially as their own profits have been getting smaller. The retail pharmacists are only too ready to lay the responsibility for the present state of affairs at the doors of the medical profession, the members of which they say are too ignorant to write a prescription and so prefer simply to order some special preparation. On the other hand, the members of the medical profession say that the reason why they so often order special preparations is that many pharmacists only keep in their shops a very inferior quality of drugs so as to make bigger profits; so lest their patients should come across such a pharmacy they prefer to order a mixture of known composition and good quality. However, the lists are open and the discussion about to take place in the Chamber will show which of the two parties is to have the advantage.

The Electrical Treatment of Gonorrhœal Arthritis.

At the meeting of the Therapeutical Society held on June 26th M. Mathieu said that everybody knew how rebellious to ordinary treatment was gonorrhœal arthritis. M. Delherm, however, had been trying a new therapeutic treatment in M. Mathieu's wards—namely, electricity. He had found that gonorrhœal arthritis could be aborted in three or four days' time by means of electricity applied to the affected parts. The treatment was tried upon six patients with 13 joints acutely affected, some of which also showed periarticular swellings. M. Delherm used a battery worked by bisulphate of manganese or of mercury cells and large electrodes, sometimes made of clay, which were applied on either side of the affected joint. A current strong enough to pass through the joint was used, the intensity varying from 20 to 50 milliampères. The sittings lasted for 15 minutes, two being given on the first day and afterwards one per diem. The effects of this treatment were very remarkable. Appreciable benefit was noticed within three hours of the commencement of the treatment and was particularly marked on the following day. The patient had passed a good night and the pains were much less; the swelling had gone down and the joint had acquired increased mobility. In most cases a complete cure was obtained in from two to six sittings, but in one case 14 sittings were necessary. There was no after-stiffness of the joint or atrophy of the muscles, as is so frequently seen in gonorrhœal arthritis. The chief point of interest, however, was the rapidity of the cure. M.

Delherm also tried the interrupted current from a coil, but the results were very inferior to the constant current from the cell.

Educational Medical Expeditions to French Mineral Watering Places and other Health Resorts.

The object of these expeditions is to afford opportunities to medical men, both French and foreign, of visiting the various health resorts of France. The French mineral water springs are grouped in various districts, and those some of the most picturesque to be found in France, hence a visit to them, as well as being instructive, is a source of pleasure. Special advantages are offered to medical students as well as to medical men who in making these expeditions subserve their own interests as well as those of their patients. The organiser of the expedition for this year is M. Carron de la Carrière, 2, Rue Lincoln. The expedition will commence on Sept. 1st and will terminate on Sept. 12th. The districts visited will comprise Dauphiny and Savoy and the various places will be visited in the following order: Uriage, La Motte, Allevard, Salins-Moutiers, Brides, Pralognan, Challes, Aix, Le Revard, Marlioz, Hauteville (sanatorium), Divonne, Saint Gervais, Chamonix, Thonon, and Évian. In 1899 the first expedition was organised, the district chosen being Auvergne and Central France. In 1900 the Pyrenees were visited. The scientific head of this year's trip will, as in the two former years, be Dr. Landouzy, Professor at the Paris Faculty of Medicine, who will deliver lectures at each station upon hydro-therapeutics. The railway companies give a reduction of 50 per cent., in the case of Frenchmen, on the ticket between the member's place of residence and Uriage, while for foreigners the reduction commences from the place of entry into the country. The same reduction is given for the return journey to the station which served as a starting-place from the last visited station, Évian. French and foreign medical men and medical students alone are eligible, but the wives of medical men may go with their husbands. The names of those intending to take part in the expedition can be received up to August 15th. They must send their names and addresses, the station from which they start, or in the case of foreigners their place of entry into France, the date of their arrival at Uriage, and their subscription (300 francs) to the Director of the Crédit Lyonnais, agence B., compte V.E.M., Place de la Bourse, Paris.

July 9th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Practitioners' Association and the Medical Union.

THE annual meeting of the German Practitioners' Association (Deutscher Aerztevereins-Bund) was held on June 28th and 29th at Hildesheim, Professor Loebker of Bochum being in the chair. In his inaugural address the President pointed out that the new regulations with respect to the medical curriculum and medical examinations were not in accordance with the wishes of the profession and that the amendments proposed by that association had not been adopted by the Government and the Federal Council. His remarks were directed especially to the facilities for becoming medical students now afforded to the pupils of Realschulen where Latin was not taught. The position of medical officers to clubs continued, he said, to be very bad and he exhorted the members to present a united front and to refrain from joining other newly founded societies, the objects of which might be antagonistic to those of the old-established Practitioners' Association. If certain members were of opinion that the work of the association was not all that could be desired it was open to them to endeavour to amend its principles and methods, but they ought not to attempt to break up the association. It was then resolved that local committees should be formed for the purpose of dealing with unqualified practice. The association will also establish an office at Hamburg where German practitioners may obtain information as to practice in foreign countries and as to vacancies for medical officers on board ship. The most important question discussed at the meeting was connected with the newly founded Medical Union (Verband der Aerzte Deutschlands zur Wahrung ihrer Wirthschaftlichen Interessen) which at the outset was diametrically antagonistic to the Practitioners' Association. The founders of the Medical Union were of opinion that the Practitioners' Association did not deal adequately with club practice. Their idea was to follow the example of the trade unions by forming a strike fund and beginning a general strike as soon as a sufficient sum had been collected. As the terms of membership were somewhat high, being one mark per week or £2 12*s*. per annum, the promoters of the movement believed that sufficient funds would soon be in hand, but unfortunately members did not come forward very quickly and the attitude of the committee by degrees became less confident. There was not now any question of a general strike; the union would only support members who had got into difficulties with a club and would take means to make the general public acquainted with the unremunerative nature of medical practice, so that a young man might not enter on a medical career without due consideration of all the circumstances. There was, therefore, now no great difference between the aims of both the old Practitioners' Association and the new Medical Union, and, indeed, the President of the latter, Dr. Hartmann of Leipsic, was present at the meeting of the Practitioners' Association in connexion with a scheme for enabling the two societies to arrive at an amicable understanding. After a long and animated discussion it was agreed that the Practitioners' Association should send a delegate to the committee of the Medical Union for the joint administration of the finances. A motion that the Practitioners' Association should recommend their members to become members of the Medical Union also was lost Another subject of discussion related to the position of medical experts in law-courts. There have been some sensational cases in which the law-courts have completely disregarded the opinion of the medical experts. In one instance an obviously insane officer had killed a comrade, and though the medical experts had declared the prisoner to be irresponsible for his actions the military court found him guilty and he was condemned to 12 years' imprisonment. The medical experts were treated after a similar fashion in a trial of malingerers at Elberfeld. On the motion of Dr. Pfalz of Düsseldorf it was unanimously resolved that the association desired to draw the attention of the Government to the position of medical experts at certain law-courts and to the scant attention which they received from the judicial authorities. The value of the Swiss preliminary examinations "for Germany" and some other subjects of less importance were also discussed.

Medical Excursions to German Spas.

Following the example of France a committee has been formed for the organising of excursions of medical practitioners to the principal spas and health-resorts of Germany. The president of the committee is Professor E. von Leyden of Berlin. The first of these excursions will be made to the health-resorts on the coasts of the North Sea and will take place after the congress of the German Association of Naturalists and Medical Men has been held at Altona. Another excursion will be made to the principal mineral water bathing-places of Germany, including Nauheim, Kreuznach, Kissingen, Homburg, Kösen, &c. The visitors will be personally conducted by Professor Baginsky, whilst the local medical men will, of course, give every information relative to the bathing and sanitary arrangements of the respective spas.[1]

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Anopheles as Host of a Trematode.

WHILE examining specimens of anopheles during the past winter in order to see whether the malarial parasite is preserved in the stomach and salivary glands of hybernating mosquitoes, Martirano[2] has made the curious observation that many of these insects act as hosts of a small trematode worm of the distomida family. The number of infected mosquitoes increases from the month of March onwards, being at first from 10 to 20 per cent., but later, in May and June, reaching as much as 50 per cent., of insects examined. It is rare to find only one worm; in the greater number of cases there are from five to 10 worms in every mosquito. They occur mostly in the posterior segment of the abdomen, sometimes also in the salivary glands; in the majority of instances the small distoma was encysted, but at other times it was free in the thorax and abdomen. The small cysts were adherent to the interior of the abdominal wall and were scarcely visible to the naked eye, appearing as white shining points varying in size from 150 μ to 230 μ. The free worm measured 1·3 millimetres in length and 0·20 millimetre in thickness. Each cyst contained only one distoma of a flat leaf-like form, oval, somewhat elongated, becoming during its active progressive movements after its liberation from the cyst narrow and ribbon-like in shape. The cuticle was thick and smooth. There were two suckers, one placed at the anterior end and another about the middle of the body on the ventral aspect. The digestive tube began at the larger anterior sucker and divided into two branches, terminating blindly. At the sides of the body two large sexual organs were generally visible, containing numerous small, rounded, yellowish-brown ova, but in many specimens these were absent. Several of the mosquitoes containing this distoma were also severely infected with filaria which were found in the Malpighian tubes. Although it is a matter of speculation both as to how these mosquitoes came to harbour the distoma and as to what the further life of the parasite may be, yet the fact of its presence in the mosquito is interesting as offering a possible explanation of the mode of infection, still obscure, of some human parasitic diseases—such, for instance, as those produced by the distoma Ringeri and the Bilharzia hæmatobia. In regard to the chief object of his inquiries Martirano found that while up to March 15th mosquitoes were infected with malarial parasites in the proportion of from 1 to 5 per cent., after that date and up to the end of May his search for infected specimens of anopheles was invariably unsuccessful.

---

[1] Further information as to the forthcoming excursion will be found on p. 94.—ED. L.

[2] Il Policlinico, Sezione pratica, Fasc. 35, June 29th, 1901.

A Case of Xiphopagus or Double Monster.

At a recent meeting of the Royal Medico-Chirurgical Academy of Naples, Corrado and Landi described a case of monomphalic monstrosity in which two female children were united to each other by a good part of the anterior surface of their bodies from the extremity of the sternum to the umbilicus, the latter being common to both. They were born on April 14th last at the village of Marianella, of young parents who had been married for one year, but the duration of the pregnancy could not be definitely ascertained. The labour was normal, the presentation was occipital in both cases, and no instruments were required. There was one placenta without any trace of division, and the cords, although really double, were united by an amniotic sheath. The children were quite lively and behaved like ordinary newly-born babies. Usually when one slept the other slept also, and when one cried the other did the same. On the seventh or eighth day of their life the child first born showed signs of suffering and a greenish diarrhœa set in, the other child at first not appearing to be affected. On the tenth day the former died and a few moments later the other, in whom similar symptoms had latterly appeared, also expired. The bodies were preserved in formalin and after being injected with different coloured injection fluids they were carefully dissected. The two thoracic cavities were found to be independent, the connexions at this point being limited to adhesions between the last costal margins. The two diaphragms were continuous and the abdominal cavities were united into one. The livers were fused at their anterior borders but each had its own gall-bladder. There were two stomachs and two duodena, the latter uniting, however, at their lower ends into a single intestine having a double line of attachment of mesentery to indicate the fusion. At the commencement of the lower fourths of the ilea the two canals again became distinct and remained so for the rest of their course.

International Congress of Physiology.

The Fifth International Congress of Physiology will take place at Turin from Sept. 17th to Sept. 20th next, when it is expected that many distinguished scientific men will gather under the presidency of the genial and versatile Dr. Mosso, professor of physiology in the Turin University. A novel and important feature of this congress will be the rule that all communications must be accompanied by experiments and demonstrations. It is proposed to devote one sitting exclusively to experimental psychology. At the last sitting Professor Marey will present the report of the International Committee appointed to control all registering instruments and to introduce uniformity into physiological methods in general. The Managing Committee consists of the following members: Mosso of Turin (President), Bohr of Copenhagen, Bowditch of Boston, U.S.A., Dastre of Paris, Hèger of Brussels, Kronecker of Berne, and Wedensky of St. Petersburg. The general secretaries are Fano of Florence, Fredericq of Lieges, Grützner of Tübingen, and Sherrington of Liverpool.

July 7th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Reorganisation of the American Medical Association.

THE meeting of the American Medical Association recently held in St. Paul, Minnesota, was in all respects a great success. The subject of reorganising that body created the greatest amount of interest and was the main topic of discussion. The committee appointed to draw up a report containing suggestions and recommendation for reorganisation seem to have accomplished this task to the satisfaction of almost all of those concerned. In the first instance it is proposed that a business section shall be constituted, to be known as the "House of Delegates," which shall proportionately represent the State societies in accordance with their numerical strength. It is suggested that the present representation for the State societies should be fixed at one delegate to every 500 members. The committee summarises the objections to the existing methods of representation as follows. 1. It is not representative. 2. It detracts from the scientific value of the annual meeting, wasting the time of those who are not interested in medico-political subjects. 3. The time devoted to the general sessions does not give opportunity for deliberate consideration of the living problems of the profession of the country. 4. The body as now constituted has become so large and unwieldy that it is impossible for it to transact business deliberately and calmly and to take up and to consider the important questions affecting the medical profession. The committee then recommend that both State and county medical societies should be uniformly organised and pertinently affirm that "no successful organisation of the profession is possible without the mutual coöperation of the national and State societies." From the temper in which the State delegates at St. Paul received these recommendations it would seem that the propositions set forth by the committee will be carried into effect in course of time. The report of the committee was accepted almost unanimously.

Congress of Christian Scientists at Boston.

There has been held recently in Boston a very remarkable meeting of Christian Scientists from all parts of the world. The gathering was cosmopolitan to a degree and representative of all grades of society. Members of the sect were present from Great Britain, Australia, New Zealand, and from other far-away parts of the globe, and earls and ladies rubbed shoulders with "persons of no account." The congress was especially important in that Mrs. Eddy showed her face to her faithful followers for the first time within several years; she also delivered an oration which was chiefly distinguished by its brevity and its obscurity. Nevertheless, her oracular sayings met with the full approbation of her audience and were, indeed, received with enthusiasm. The figures given of the growth of the "mother church" reveal an astonishing and significant state of affairs. The membership in Boston alone reaches the respectable total of 21,631—a gain of 2496 since November. In all America the cult has more than 500 organised churches, the congregations of many of which have erected really imposing structures at great cost, notably in New York and Chicago. The progress of Christian Science is perhaps the most remarkable of any religious movement during the last few years and is mainly impressive for the reason that educated and otherwise sane individuals are eagerly embracing its tenets. Undoubtedly Christian Science in America is pressing heavily upon an already severely handicapped medical profession, but that any restriction will be placed upon its teaching by legislation would seem in the present temper of the American public to be an illusive hope.

Gift to Harvard Medical School.

American multi-millionaires and millionaires seem to have developed of late a healthy emulation in giving for the purpose of education. Spurred on, perhaps, by the example of Mr. Carnegie, in quick succession Mr. Rockefeller and Mr. J. Pierpoint Morgan have made magnificent gifts for the advancement of medical science. At the annual dinner of the Alumni Association in Memorial Hall at Cambridge, Mass., on June 27th, President Eliot read a cable message from Mr. Pierpoint Morgan in which he promised to provide funds for the erection of the new buildings needed by the Harvard Medical School. The three buildings in question are intended as a memorial to Mr. J. S. Morgan who commenced his business career as a merchant in Boston and who died a merchant in London. It is said that the buildings will cost $1,000,000 (£200,000). The outlay on the entire new medical plant will reach the large sum of $2,000,000 (£400,000). The money provided by Mr. Morgan is to be expended for the furtherance of applied biological research.

Small-pox in the United States.

This disease is very prevalent more or less throughout the United States. The epidemic has been and is still of a mild type, as is shown by the fact that although the cases are far more numerous than at the same period of last year the mortality is less. In Minnesota in the week ended June 15th 4679 cases were reported; in Tennessee, 4323; in Kansas, 4078; in Colorado, 2197; in Ohio, 1965; in New York, 1219; in North Carolina, 845; in Indiana, 834; and in Nebraska, 790. The total number of cases reported in the week ended June 15th was 28,257 with 486 deaths. In the same period in 1900 there were 12,092 cases with 642 deaths.

July 2nd.

Medical News.

UNIVERSITY OF BIRMINGHAM.—The following candidates were successful at examinations held in the Faculty of Medicine in June:—

1.—FOR THE DEGREES OF BACHELOR OF MEDICINE AND BACHELOR OF SURGERY.

(a) *Associates.*—Henry William Langley-Browne, Edward Cureton, Charles Leedham-Green, Jordan Lloyd, David Charles Lloyd-Owen, Priestley Smith, Thomas Law Webb, and Edmond Bancks Whitcombe.

(b) *Past Students of the Birmingham Medical School.*—George Clement Belcher, Reginald Shirley Burd, Arthur Cant, Gilbert William Charsley, Arthur Emery, Thomas Webb Fowler, John Edward Godson, Frederick James Vincent Hall, Charles Harold Harcourt, Arthur Hawley, George Leonard Hill, Wilfrid Anthony [illegible] Arthur Wilkes.

(c) *Under Ordinary Regulations.*—Michael Joseph Quirke.

2.—FOR THE DEGREE OF BACHELOR OF DENTAL SURGERY.

(a) *Associate.*—John Dencer Whittles.

(b) *Past Student of the Birmingham Dental School.*—Harold Round.

3.—FOR THE DIPLOMA OF PUBLIC HEALTH.

Robert Arthur Lyster and Robert Turner.

FIRST EXAMINATION FOR THE DEGREE OF BACHELOR OF MEDICINE AND BACHELOR OF SURGERY.

Elementary Biology (Part I.).—Henry Neville Crowe, Harvey Atkins Evans, Richard Stuart Wathen Hunt, George Frederick Jothan, and Norman Valentine Williams.

Chemistry and Physics (Part II.).—*Class I.:* Francis Reginald D'Alton Glissan and Norman John Lancelot Rollason. *Class II.:* Robert Wallace Aitken, Reginald Hudson Astbury, Edward Lancelot Bunting, Helen Gertrude Greener, Leonard Leigh Hadley, William Claude Horton, William Cuthbert Houghton, and Henry Percy Pickerill.

SPECIAL SECOND EXAMINATION FOR THE DEGREE OF BACHELOR OF MEDICINE AND BACHELOR OF SURGERY.

Class I.—Alfred Ernest Remmett Weaver and Frederick Wilkinson.

Class II.—William George Aviss, William Cook, Cuthbert Keay Gettings, Robert Beatson Dennis Hird, Leonard George Joseph Mackey, and Edmund Wilkinson.

SOCIETY OF APOTHECARIES OF LONDON.—At the primary examination held recently the following candidates passed in the subjects indicated:—

PART I.

Biology.—G. E. Austin, Royal Free Hospital; F. C. M. Gabites, Edinburgh; and C. A. Sampson, Charing Cross Hospital.

Chemistry.—G. E. Austin, Royal Free Hospital; and F. C. M. Gabites, Edinburgh.

Materia Medica and Pharmacy.—A. Bernfeld, Royal Free Hospital; A. G. Gamble, Leeds; G. B. Messenger, Liverpool; C. A. Sampson, Charing Cross Hospital; C. J. Taylor, Bristol; and B. B. Westlake, Guy's Hospital.

PART II.

Anatomy.—A. J. Ambrose, Westminster Hospital; G. C. M. Davies, Charing-cross Hospital; B. C. Ghosh, and T. W. S. Hills Cambridge; H. M. Huggins, St. Bartholomew's Hospital; C. Kellgren, Royal Free Hospital; G. Nunn, Guy's Hospital; C. H. Osmond, Glasgow; O. P. N. Pearn, Westminster Hospital; E. H. Price, Birmingham; R. C. Richards, University College Hospital; R. J. S. Verity, Charing-cross Hospital; and S. J. Weinberg, Manchester.

Physiology.—H. Bacon, Cambridge and Guy's Hospital; G. C. M. Davies, Charing Cross Hospital; B. C. Ghosh and T. W. S. Hills, Cambridge; H. M. Huggins, St. Bartholomew's Hospital; A. C. Jenkins, London Hospital; T. L. A. Jones, Cardiff; C. Kellgren, Royal Free Hospital; G. Nunn, Guy's Hospital; O. P. N. Pearn, Westminster Hospital; E. H. Price, Birmingham; G. H. Rains, Westminster Hospital; R. C. Richards, University College Hospital; and S. H. Sugden and S. J. Weinberg, Manchester.

FOREIGN UNIVERSITY INTELLIGENCE.—*Bordeaux:* Dr. Sigalas, *agrégé*, has been appointed to the new chair of Pharmaceutical Physics. Dr. Gentès and Dr. Cavalié have been appointed *professeurs agrégés* of Anatomy; Dr. Benech, *professeur agrégé* of Chemistry; and Dr. Dupony, *professeur agrégé* of Pharmacy.—*Cracow:* Dr. Karl Klecki, Extraordinary Professor of General and Experimental Pathology, has been appointed Ordinary Professor.—*Freiburg:* Dr. Wilhelm Manz, Professor of Ophthalmology, is retiring from his chair.—*Lille:* Dr. Gérard has been appointed *professeur agrégé* of Anatomy.—*Lyons:* Dr. Regaud has been appointed *professeur agrégé* of Anatomy.—*Marburg:* Dr. Borrmann, first assistant in the Anatomical Institute, has been recognised as *privat-docent.*—*Montpellier:* Dr. Poujol has been appointed *professeur agrégé* of Physiology.—*Paris:* Dr. Rieffel and Dr. Cunéo have been appointed *professeurs agrégés* of Anatomy, Dr. Guiart *professeur agrégé* of Natural History, and Dr. Richaud *professeur agrégé* of Pharmacy.—*Prague (Bohemian University):* Dr. Okukula has been appointed Extraordinary Professor of Surgery.—*Rostock:* Dr. Keller of Breslau has been appointed Extraordinary Professor of Children's Diseases.—*Toulouse:* Dr. Cluzet has been appointed *professeur agrégé* of Medical Physics.—*Vienna:* Dr F. von Sölder has been recognised as *privat-docent* of Psychiatry and Neurology.

CERTIFICATION OF LUNATICS.—A meeting of the magistrates of the Taunton Petty Sessional Division was held on June 22nd to consider a report from one of the magistrates in reference to a case of lunacy which had come under his notice. This stated that a relieving officer called upon this magistrate recently with a request that he would sign an order for the detention of a lady in a lunatic asylum. The officer said that two medical men had already certified the lady to be insane and added that he "must sign" the order, and "that if he should not do so he would be answerable for the lady's life if anything happened to her." The magistrate then consulted the magistrates' clerk who found that this mode of procedure was irregular because the relieving officer had not obtained from a magistrate the formal necessary orders directing two medical practitioners to examine the patient and had asked the justice to sign the order for removal, it being not only necessary for the medical men to certify insanity, but the justice himself must be satisfied with the evidence. The bench of magistrates decided that in future they would not sign any such order unless the law had been fully complied with. The clerk to the guardians said that the relieving officers had been in the habit of calling in medical practitioners and getting their certificates, and the magistrates had until now been satisfied with those certificates

LITERARY INTELLIGENCE.—The Syndics of the Cambridge University Press have undertaken the publication of the first part of the "Index Animalium," to the preparation of which Mr. C. Davies Sherborn has devoted so many years. The object of the index is to provide zoologists with a complete list of all generic and specific names given by authors to animals, both recent and fossil, since Jan 1st, 1758, the date of the tenth edition of Linnæus's *Systema Naturæ*. With each name will be given an exact date and a reference intelligible to the layman as well as to the specialist. The British Association appointed a special committee to watch over the inception and progress of the work, the preparation of which was undertaken in 1890 Financial support has been given by the British Association, the Royal Society, and the Zoological Society, while the authorities of the British Museum have afforded continual assistance. The work will be to the student of animal life what the "Index Kewensis" is to the botanist, and indeed far more, as the last-named work refers only to phanerogams, whereas the "Index Animalium" will include all groups of animals and both recent and fossil forms. The portion of the work already completed and in the press covers the period from 1758 to 1800 and consists of 61,600 entries.

Society for the Study of Disease in Children.—Some 70 members and visitors attended the provincial meeting of this society, which was held on June 29th at the Medical Institution, Liverpool, under the presidency of Mr. Robert Jones, surgeon to the Royal Southern Hospital. 31 new members were elected. Many interesting clinical cases were shown and papers were read by Dr. Henry Ashby, Dr. George Carpenter, Mr. Sydney Stephenson, Dr. D. M. Hutton, Mr. K. W. Monsarrat, Dr Richard Caton, Dr. C. J. Macalister, Mr. R. Clement Lucas, Dr. John H. Bryant, Dr. John McCaw, and Dr. James Carmichael. In the evening the members dined together at the Adelphi Hotel, Dr. A. Ernest Sansom being in the chair. The toast of "The Society" was proposed by Dr. William Carter, physician to the Royal Southern Hospital. On the following day the members drove to Heswell for the purpose of inspecting the new building of the Liverpool Country Hospital for Chronic Diseases of Children, and afterwards they lunched with Mr. Robert Jones.

Presentations to Medical Practitioners.—At Totnes railway station on July 5th, after the distribution of certificates and badges awarded to the members of the Totnes and Brent branch of the St. John Ambulance Association, which consists of the employés of the Great Western Railway Company, Mr. H. Adye, the divisional superintendent, on behalf of the class, presented Mr. W. Richardson Edmond, M.B. C.M., L.R.C.P. Edin., M.R.C.S. Eng., and Mr. J. William Wyncoll, M.B., C.M. Edin., with a case of pipes and a silver-mounted walking-stick, respectively, in appreciation of their services as honorary instructors.

The late Dr. A. L. Wade.—Dr. Arthur Law Wade, who has been for several years physician and superintendent at the Somerset County Asylum, near Wells, died suddenly on July 1st. Dr. Wade, who graduated M.D. of Dublin in 1873, had formerly held the appointments of senior assistant medical officer at the Kent County Asylum and at the Warwick County Asylum, of surgeon to the Royal Isle of Wight Infirmary, and of assistant medical officer at the Laverstock House Asylum, Salisbury. Dr. Wade, who was well known in Wells and the neighbourhood, was held in high esteem by all classes and much regret is felt at his death.

Weston-super-Mare Hospital.—A successful *fête* was held on July 3rd and 4th in aid of the funds of the Weston-super-Mare Hospital and it is thought that the institution will benefit to the extent of about £600.

Deaths of Eminent Foreign Medical Men.—The deaths of the following eminent foreign medical men are announced:—Dr. Julius von Siklossy, ophthalmic surgeon to the St. Rochus Hospital, Budapest.—Dr. Gino Ciaccio, Professor of Comparative Anatomy in Bologna.

Medical Magistrate.—Dr. William Moxon of Matlock Bridge has been placed on the Commission of the Peace for the county of Derby.

Parliamentary Intelligence.

HOUSE OF COMMONS.

THURSDAY, JULY 4TH.

The Army Medical Service.

DR. FARQUHARSON asked the Secretary of State for War whether the Committee on the Army Medical Department would take evidence and whether it would be allowed to suggest alternative schemes to that proposed by the chairman; and whether its proceedings would be public.—Mr. BRODRICK replied: No; so far as at present arranged the committee will not take evidence and its proceedings will be private. It will, of course, be open to any member of the committee to submit alternative proposals.

Sir CHARLES DILKE asked the Secretary of State for War whether the committee of experts to consider the future organisation of the Army Medical Service would take into consideration the arrangements to be made in time of peace for utilising in time of war the services of civil surgeons and trained civilian nurses in connexion with the Army Medical Service; and would he state what would be the reference to the committee.—Mr. BRODRICK replied: The committee will be invited to consider the general medical requirements of the army. The committee is a consultative committee, and I do not propose to publish terms of reference.

FRIDAY, JULY 5TH.

Hospital Ship for the Mediterranean.

In the course of a debate on the shipbuilding vote for the Navy it was announced that the Admiralty had intended to hire a hospital ship for the Mediterranean Squadron, but it would not be necessary to do so now owing to the gift to the nation of the hospital ship *Maine*, which in due course would take her place as the hospital ship of the Mediterranean. The Admiralty, however, were taking money for the provision of a large amount of equipment for hospital ships in the event of war. The view of the Admiralty was that they should not actually equip more hospital ships than were necessary in time of peace.

Royal Commission on Sewage Disposal.

Mr. WALTER LONG, in reply to a question, said that he understood the Royal Commission on Sewage Disposal had agreed to an interim report and he hoped that this report would be issued very shortly.

MONDAY, JULY 8TH.

Sickness among the Troops in South Africa.

Lord STANLEY, in reply to Mr. MACNEILL, said that there are 251,000 troops in South Africa of whom about 14,000 are sick. There were no returns which enabled him to give any detailed information.

TUESDAY, JULY 9TH.

First Aid and Home Nursing in Evening Schools.

Dr. MACNAMARA asked the Vice-President of the Committee of Council on Education whether he would state why the subjects of first-aid, home nursing, and physical exercises, including gymnastics and swimming, had been *dropped* in the Evening Schools Minute of July 3rd.—Sir JOHN GORST replied: Because of the abuses to which the inclusion of "suitable physical exercises" has given rise. Some of the subjects mentioned in the question would probably be sanctioned under the fifth head of Group VIII.

THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

SPECIAL GENERAL MEETING OF GOVERNORS AND SUBSCRIBERS.

THE governors and subscribers of the National Hospital for the Paralysed and Epileptic held a special general meeting on Saturday last, July 6th, in the hospital to receive and to consider the report of the committee of inquiry appointed pursuant to the resolutions passed on March 23rd. The chair was taken by Mr. PEARMAN and he was supported by a few members only of the Board. The attendance of governors and subscribers of the charity was not so great as on March 23rd, numbering about 70.

The CHAIRMAN having invited Mr. Melvill Green to propose the motion, of which notice had been given, Mr. MELVILL GREEN commenced by moving the thanks of the meeting to the *gentlemen* who had made the report. He proposed that the best thanks of the governors be given to Sir Edward Fry, Lord Wolverton, Mr. W. W. Carslake, Mr. Timothy Holmes, and Mr. Cecil Henry Russell, together with Mr. John Danvers Power, the honorary secretary, for their valuable services in conducting the *inquiry* of *investigation*.—The motion was seconded by Mr. WALFORD and put to the meeting and carried unanimously.

Mr. MELVILL GREEN: I come to the duty which has been imposed upon me of moving the first of three motions of which notice has been given—namely, that the report of the committee of inquiry be adopted. For that *motion*, of course, the committee of which I am a member are responsible. What I say now of the report is that for which I am only *responsible*. I hope I shall not offend anyone, for I contemplate reading certain portions of the report so as to make intelligible my remarks. I should like to read first of all Clause 13 in which the committee say that they have inquired into the truth of the several allegations complained of in the statement of the medical staff and they find that some of the most important of them are true, that some have a foundation of fact but are exaggerated, and that others are unsupported by any sufficient evidence. And then I should like to read Clause 53: "We can find no foundation for the fears entertained that the character of the hospital as a religious and philanthropic institution will be imperilled by the presence of two medical men on the Board of Management, and we are therefore quite unable to concur with the present Board when they characterise the demands of the medical staff as 'encroachments calculated to destroy the religious and philanthropic character of the hospitals, and to subordinate to purely professional objects institutions maintained by the benevolent for benevolent purposes.'" In Clauses 50 and 51 they say this, and this is a very important topic: "Another of the objections urged to the direct representation of the medical staff on the Board of Management is that it would give undue influence to the scientific elements in the hospital and will tend to subordinate the immediate benefit of the patient to the pursuit of medical knowledge." They inves- [illegible] nothing was adduced [illegible] or the action of the [illegible] suspicion suggested as [illegible] is our opinion that the defects in management to which attention was drawn by the statement were deserving of notice and correction; but that they were never *sufficient in magnitude and frequency to render the treatment in the* hospital otherwise than good as a whole." These four passages seem to me to show that what I ventured to say last August in a very much thinner meeting than we have here to-day is quite true—namely, that both sides had exaggerated but that there was truth with both. But they are very satisfactory statements to us as governors—very satisfactory indeed, because they show both that fears are unfounded and that the amount of mischief done to the hospital is not of an important character. It is trivial. I should like also to refer to the subject of finance. When it is mentioned that there are irregularities in finance people are apt to get frightened. It is true there were irregularities in finance. There ought to be three trustees and there are only two—that is a mere technical detail. A sum of money has been placed to one account that ought to have been placed to another—that is to say, it has been invested in what it ought not to have been, but the matter of finance is absolutely all right in the popular sense of the word. I must come now to the business of the day. The object of this report is to effect a very great and important change in the manner of managing this hospital and I trust you are going to—I am told there will be no difficulty on the matter—adopt the motion unanimously. I think it is inevitable that we shall do so The supervision of the affairs of the hospital by the Board of Management has not been adequate to the needs of the institution. The report says so and by adopting the report we say so. The rule of the hospital is *that there shall not be less than 12 members of the Board.* There are no more, but one or two members, in consequence of their personal distinction or their past services, in consequence in fact of most excellent reasons have been retained upon the Board when they have not been able to give attention to its affairs Most institutions have gentlemen of that kind on the Board. There are two, or more than two, courses open You can have a large committee of management and put asterisks against the honorary members or you can have a body of vice- [illegible] when they like; but the [illegible] the names of gentleme [illegible] of allowing their owner- [illegible] men on whom the ma [illegible] years to be able to giv [illegible] system and one of the [illegible] brings me to the two m [illegible] In Clause 55 we have [illegible] the report, "that the Board of Management be increased by the addition of two members chosen by the medical committee from the medical staff." And in Clause 48, "we are of opinion that the mode of representation desired by the medical staff is a very proper one and is the smallest concession which is reasonable." By carrying the motion that I am submitting to you [illegible] these must be altered at some subsequent [illegible] ond motion which is to be put before [illegible] prepare this alteration. By adopting the report I hope it is quite understood that we decide beyond all controversy and question that the medical staff shall be represented by two of its members elected by itself on the Board. The second [illegible] as follows: [illegible] in the hos- [illegible] there is such [illegible] ch an office. [illegible] a appointed with that title. I do not think that after receiving the resignation of Mr. Burford Rawlings which we have already in our hands, [illegible] that there be no secretary-director [illegible] this office and the appointment of [illegible] to seats upon the Board of Management are two subjects that have been in controversy for 15 or more years. They are the two main points of the controversy. The report shows you how fit it is that these reforms should take place In Clause 67 the action alike of the secretary-director and of th [illegible] to hinder the free acce [illegible] the Board. That is [illegible] 69 we have extraor [illegible] point, and I will t [illegible] *forcibly than the* [illegible] he pursued in the case dealt [illegible] dealings with the medical [illegible] the Board of Management" [illegible] proves this—"that, in our [illegible] manner which he thought to [illegible] of the instruction which he received from the Board; and that on them rather than on him rests the responsibility for the attitude he assumed towards the medical staff". My whole soul goes with that clause. There is nothing to blame Mr. Burford Rawlings for except that he did not perceive the falseness of his position He acted according to his directions and did what the Board wanted him to do and the blame, if blame there be, rests with the Board. I feel very sorry about the situation. Here is a gentleman who, with mistakes or without (it does not matter), has devoted the best of his life to the service of the hospital and who has done for it a great deal of very excellent work, who has devoted to it his life and whose heart has been in it. And yet we are obliged to take such a course that he must retire. It is pathetic; I feel very sorry about it; but I ask [illegible] I understand that the members [illegible] give us an explanation whic [illegible] does not appear to have bee [illegible] of inquiry. I do not want to say anything disagreeable. I do not want to suggest that the members of the Board should resign. I do not want to suggest that you, the governors, should say so, because the governors have no power. They can only elect two members, after three months' notice, before an annual meeting the date of which you do not know. In the course of six years you can change the Board and in the course of four years you can change the majority. That is one of the things which has to be altered in the rules. The members of the Board have told us for some time with great vigour that it would be quite [illegible] *members of the medical staff* [illegible] members of the staff would d [illegible] have to give way to the staff [illegible] that they cannot so conduct [illegible] withstanding the opinions that they have entertained and expressed so strongly, are willing still to govern the hospital with rather more industry, though, perhaps, not with more heart, than formerly I have nothing to say to it and certainly the report says nothing. The medical staff should now elect two members to the Board. There should be no secretary-director. The rules have to be revised from beginning to end. In Clause 107 [illegible] revising and the one or two claus [illegible] There are several matters which [illegible] some day—for example, payme [illegible] proxy There are questions alsc [illegible] many of these things will right themselves by the presence of two of the medical staff on the Board. I do not wish to refer to other details. I hope you are going to vote for the adoption of the report and so absolutely decide the three points: that the staff shall be represented on the Board, that the office of secretary-director shall be abolished, and that the rules shall be revised.

Sir JAMES CRICHTON BROWNE: I beg to second the adoption of the report. The committee have performed the duty assigned to them in the [illegible] practicable It is impossible thoroughly to grasp the significance of this report without comparing paragraph by paragraph the statement of the medical staff made in 1890 with the report of the sub-committee of management appointed to inquire into the complaints made in that report. Any such minute and detailed comparison, however, is [illegible] able, for it cannot [illegible] al staff have been [illegible] the sources from [illegible] pital have arisen. As far as possible we should avoid recrimination. There should be no [illegible] order that it may be restored we have to give it our support at a [illegible] sure every membe [illegible] in so many other [illegible] views and have [illegible] unfortunately ha [illegible] upon the gratitu [illegible] Mr. Melvill Green says, been a devoted servant to the hospital for 33 year [illegible] service, and has drawn [illegible] pecuniary support. And if [illegible] you owe a tenfold debt o [illegible] ave not only given their p [illegible] ave saved it from ruin. [illegible] re would have been [illegible] committee of inquiry there [illegible] hese abuses which have been [illegible] This must have resulted in [illegible] of this hospital into a posi- [illegible] I beg leave to second the [illegible]

[illegible] to ask permission to say a few [illegible] before the meeting, and to exp [illegible] the opinion of a great number [illegible] unfortunately not here to-day [illegible] may remark that to call a meeting of this kind of such very great importance on a day like this, on a Saturday and at this hour, makes it almost impossible for a great number of the subscribers to be present and it requires a certain amount of sacrifice for those who are here to be present We are here to-day to receive the report from the committee of inquiry who have, I doubt not, taken the very greatest pains to carry out the mandate given to them and we are told that it is our bounden duty to receive it without discussion, to adopt it entirely, and consequently to adopt every recommendation that is in it. I do not think that even the majority of the whole of the supporters of this charity would hold that view. As far as my own opinion goes it has always been that for the Board to maintain that the addition of two members of the medical staff to its numbers—two out of 12—would involve the predominance of medical influence on that Board was ridiculous. But it is not the business of the medical staff to govern the lay affairs of the hospital. Mr. Burford Rawlings is a man of obviously great ability and I for one would be very sorry if the adoption of this report should involve the severance of his name from the hospital, for good men are not so very easily found, and when we get them, even though with some faults which require to be amended, the way to get out of the difficulty is not by their dismissal. The working of a hospital is a large business and there is no business in the world that could be carried on successfully by a Board of 12. At one meeting some would attend, at the next others would attend, and so on, consequently there would be no sequence or method in the way in which the administration of the hospital was conducted. How could that plan possibly succeed? Is it not necessary that the Board should be represented by somebody who shall gather together the wishes of the management and see that they are carried out? I really cannot see how a Board can conduct a large business and deal with the many questions that must inevitably come before the hospital. The other alternative is to appoint a medical man, as I take it, as the head of the whole hospital and let him have the power (loud cries of "No, no").

Mr. **Walford**: It seems to me that it is not for us to discuss these points which are for the committee to be appointed.

The **Chairman**: It appears to me that the speaker is dealing with a paragraph of the report and is in order.

Mr. **Nelson**: I understand that some medical gentleman is practically to take the place that Mr. Burford Rawlings is about to vacate. (Renewed cries of dissent.) *What I want to insist upon is that if we* adopt this motion we are not bound to carry out all the recommendations contained in the report. We are not pledged to do that but we are pledged to consider it.

Dr. **Bastian**: There is no definite recommendation made, but there are two alternative schemes. It lies obviously with the committee that is about to be appointed to look into the details and when the committee have arrived at their conclusions their report will come before a subsequent meeting of the governors.

The **Chairman**: I quite agree with you.

Mr. **Melvill Green**: The second motion is: "That a committee be appointed to represent the governors in ma[illegible] may be necessary for dealing with all matt[illegible] arising out of, the adoption of the previous [illegible] widely worded. Of course, it means first that the committee will consider the whole management and constitution of the hospital and that they will at another meeting of the governors consider such alterations in the rules or such other matters as may require their decision; but I think the motion goes a little further. It does not say that the committee be appointed only to do that, but to represent the governors in making such arrangements as may be necessary for dealing with all *matters consequential* upon, or arising out of, the adoption of the previous resolution. I am not quite sure what it does do. It may be that it confers upon the committee we are about to appoint power to do temporarily what the governors do permanently in the interval. It seems to be a matter of considerable importance. It is quite impossible for the governors to meet again before October at the very earliest—it is out of all practical question; and I think this committee have conferred upon them a very great amount of power. That is my construction of the resolution, and I take this opportunity of pointing it out. You can see the words for yourselves and can judge. This motion seems necessary and I think the Board agree with us that a wide resolution of this kind is better. You must trust the committee you nominate [illegible]gs out of the governors' hands which would [illegible] position. I propose this motion.

[illegible] I second the motion subject to the addition of one or two words that are absolutely necessary. These words must be added, "reporting their recommendations to the governors." Surely what is to be done in the shape of reconstituting the constitution of the hospital must be done by a decision at a meeting of the governors; and while the governors certainly could not grapple with such a large subject you will agree with me that the committee should certainly report to the governors their recommendations.

Mr. **Melvill Green**: Certainly, if anyone thinks it is desirable, but the words are absolutely unnecessary. This meeting has not the power to rescind rules, much less can a committee appointed by it have power to rescind rules. The rules can only be rescinded by a meeting of the governors called for that purpose. That is quite certain and goes without saying.

A **Governor**: If so, why not say it?

Sir **Sydney Waterlow**: If you accept the words "reporting to the governors their recommendations and actions" I second the motion. I do not think I need say anything more except to congratulate the Board of Management and the governors generally upon the decision at which we have arrived after a long, wearying, and to me a very unpleasant and tiresome discussion. I hope that the committee that is to be appointed will frame such a new constitution as will be a permanent benefit to the institution and will bring into harmony the staff and the governing body.

Mr. **Victor Horsley**: May I ask a question relative to the duties of the committee? It is with regard to the expenses of the inquiry. I am anxious on behalf of the charity that this charity should not be [illegible] taxed for this horrible dispute.

The **Chairman**: I think the question is *hardly in order* on this reso[illegible]. This proposal has nothing to do with these expenses.

Mr. **Victor Horsley**: I was going to ask whether the committee [illegible] going to take into consideration that paragraph in the report that [illegible]fers to the expenses of this inquiry? The medical staff have not put [illegible]he hospital to a single halfpenny of expense and the Board have involved and are involving it in the expenditure of hundreds of pounds. I want to know on behalf of the patients for whom the hospital is carried on whether the charity is going to be taxed or not; that is my point.

The **Chairman**: I do not wish to interrupt you; I do not think you are in order at this moment. You are addressing yourself to a recommendation of the committee of inquiry.

Mr. **Victor Horsley**: Excuse me, sir, I am simply asking whether the committee of organisation will deal with this paragraph 109 and bring it before a general meeting.

The **Chairman**: It will deal with the whole of the report.

Mr. **Victor Horsley**: Very well, that answers my question.

Sir **John R. Paget**: May I point out that Clauses 103 and 109 of the report deal specifically with the matter. It is perfectly open to Mr. Victor Horsley or anybody else to bring up before this meeting the question of the expense of the inquiry.

Mr. **Melvill Green**: *I think* that the proper motion for Mr. Horsley would be to suggest that these costs should be taxed.

Mr. **Bowers**: I have given an undertaking to the committee of inquiry, being the solicitor in question, to agree that my bill shall be taxed if necessary. *They requested me to write a note to that effect,* and I said "Certainly." I did so at once. If there is the slightest indication on the part of any governor that the bill should be taxed I shall be glad if that course is taken without debate.

Mr. **Nelson**: Has Mr. Rawlings sent in his resignation to the Board?

The **Chairman**: Mr. Rawlings has notified his resignation for the next meeting of the Board.

Mr. **Nelson**: Is it open for the Board to consider its acceptance?

Mr. **Wigan**: I cannot assent to that.

The **Chairman**: *The Board are in the hands of the governors and* the Board would undoubtedly feel bound by any decision to which the governors may arrive at at a special general meeting, but speaking generally the Board are in a position to accept or to refuse the resignation.

Mr. **Melvill Green**: Technically that is so. I have talked the matter over with Mr. Bowers and we both came to the conclusion that it was quite impossible to retain Mr. Rawlings's services, anxious though I am that this should be done, but there was no mode possible by which it could be done.

Mr. **Bowers**: That is so.

The **Chairman**: I think it is very undesirable that any actual decision of this sort should be come to at this meeting. It is a subject for discussion connected with the report.

Mr. **Wigan**: I must again say that I understood that in adopting the report we accepted Mr. Rawlings's resignation. I do not want there to be any misunderstanding about that.

The **Chairman**: I think there must be some misunderstanding and I will clear it up. The Board a short time ago had a meeting with the committee of selection and it was then arranged after talking the matter over that in order to bring peace into this institution—a condition of things which has been absent from it some time—that it would be well, if the governors thought proper, that the Board should assent to the recommendation of the committee of inquiry so far as it related, first of all, to the admission of two members of the medical staff to the Board and, secondly, to the abolition of the office of secretary-director. That, I take it, is the main part of the report. There are other recommendations. There are other things which more or less, perhaps, look like condemnations. I have heard with some surprise that a good deal of blame has been attached to the Board and that the committee of inquiry have thrown on them more blame than on Mr. Rawlings. I think you will find if you will refer to the report of the committee of inquiry that upon the whole their opinion as to the condition of the hospital is good, that the management has been satisfactory (cries of "No, no"). Well, I will read the report as I hear somebody dissent: "Two surprise visits to the hospital have been paid by members of our committee, and we have thus made a personal inspection of the whole of the institution and instituted inquiries on the spot into various matters connected with its management. Generally speaking, the hospital was in good order." That is one clause. In another clause, which I cannot put my hand on this *moment, I think you will find they say, "We have inquired into the* truth of the several allegations made by the medical staff, contained in the statement of the staff, and we find that some of the most important of them are true, that some of them have a foundation of facts, that some are exaggerated, and that others are unsupported by any sufficient evidence. It is our opinion that the defects of the management to which attention was drawn by the statement were deserving of notice and correction but they were never sufficient in magnitude and frequency to render the treatment of the hospital otherwise than good as a whole." In other words, this hospital, like all other human institutions, had its failings. I have no doubt it had. The Board certainly do not profess to be immaculate. They do not claim that their management is absolutely perfect in every respect, but they do claim, and I think that they also have some right to claim, that the hospital is what it is in consequence largely of the action of the Board of Management. Some 25 to 30 years ago, when I was introduced to this institution by one of the founders, the charity was carried on in two little houses in Queen-square. Mr. Rawlings, of whom so much has been said, was then the secretary to the institution. From that time to this the hospital has continued to advance. The medical staff, whatever their feelings may be as to various matters, will not deny that they have from time to time and from year to year, when we have had our festival dinners expressed themselves as perfectly satisfied with the conditions of the hospital and with its advance. There has certainly been no hospital in this country which has increased at a greater rate or attained a greater name than this. No doubt that great name is largely due to the eminence of its medical staff. I for one should be very sorry to attempt to deny the medical staff the honour which is their due, but, on the other hand, the Board of Management claim that some credit is due to them even for the appointment of the medical staff. *It is a very important matter to appoint a medical staff,* and the Board of Management claim that in their selection they have chosen men who have been a credit to the institution. I think you would find that if an investigation were made in respect of any charity in this country, where the prosecution, if I may term it so, was undertaken by the medical staff, who have an intimate knowledge of all matters of the hospital, if every detail of management were questioned, if every fault that could be pointed out were pointed out to a committee of inquiry composed as this committee of inquiry was, I think that you would find that no institution would come out of that inquiry with a better report than this. I fully expect the medical staff will agree with me in what I say (cries of "No, no"). The defects, such as they are, which have been pointed out by the committee of inquiry, the most important of them at least, are those which were not brought to the knowledge of the Board (cries of "Oh"). I do think that, notwithstanding what is said by the committee of inquiry, and I can hardly think the medical staff themselves can be disposed to deny much that they ought to have brought these matters before the Board (loud cries of "We did"). All I can say is this, speaking for myself as one member of the Board of Management who has attended practically regularly for the last 35 years that these defects were not brought to my knowledge and I cannot help feeling that if they had been brought to the knowledge of the Board as a whole that it is absolutely impossible that I should not have heard of it. I do not propose to delay the meeting with any long expression of opinion on my part. The governors are proposing—and it is quite a proper course—to defer the questions which have been decided to a committee of their own number, and I will therefore put the resolution unless any other governor would like to address the meeting.

Mr. Victor Horsley: In the name of the staff I beg to protest against [illegible] to the [illegible] matter [illegible] inspire [illegible] Pearman comes here and has the [illegible] ical staff has not done this very [illegible] f the medical staff against your [illegible]

The Chairman: In replying to Mr. Horsley, I hope he will not suggest that I intended to be disingenuous. What I said was if any notice of these complaints had been given to the Board I do not see how it was possible that I, as a constant attendant, did not know of it and I individually did not know of it.

Mr. Victor Horsley: I must accept your explanation, but I do not consider it satisfactory.

The Chairman: Excuse me a moment. Though I do not think it desirable to continue the discussion I should like to read the thirty-ninth clause of the report.

Sir Sydney Waterlow: I rise to call the meeting to order. Does this discussion arise out of the motion for the appointment of the committee?

The Chairman: Though we are somewhat irregular I will ask you as a personal matter to allow me to read this thirty-ninth clause of the [illegible] that the Board of Management have [illegible] of sufficient bed-linen, and that the [illegible] ieral director has been directly drawn [illegible] o the condition, care, and treatment [illegible] s have been taken to remove them. [illegible] gment, not been proved." [illegible] have no further discussion which is [illegible] l with the past, let it be dead. We cannot alter it, we are concerned with the future that is in our hands

Sir James Crichton Browne: Clause No. 77 should be read also, otherwise it is unfair to Mr. Rawlings, whose case will come up for consideration, and one is bound to point out that the Board have for [illegible] the appr [illegible] opinion [illegible] be his du [illegible] received from the Board, and that on them rather than on him rests the responsibility for the attitude he assumed towards the medical staff."

The motion was put to the meeting in the amended form and carried unanimously.

Mr. Melvill Green: The third motion is that such committee consist of nine persons, three [illegible] Management, two by the [illegible] appointed on March 23rd, a [illegible] not propose that they shou [illegible] perhaps be surprised that [illegible] Board has the power of no [illegible] say it is desirable to keep t [illegible] have expressed themselves a [illegible] Board it has been suppose [illegible] number on the committee.

Sir Sydney Waterlow: I second this.

Mr. Melvill Green: Some alterations have been suggested by Mr. Bowers which are an improvement. He suggests that such committee consist of nine persons, three of whom shall be appointed, not [illegible] he appointment is [illegible] to the governors, [illegible] appointment was [illegible]

Sir Felix Semon: May I say one word before voting on behalf of the medical staff? We agree to this very much against our wish and we agree to it really in the interests of peace. It would have been better if this committee had been constituted by the governors without any delegates from the Board or medical staff, just in the same way as the committee of selection was appointed. It would have been open to that committee to ask for technical references from the Board and from the staff. We very much fear that a Board constituted in the manner proposed will simply be a repetition of what has happened on previous occasions. We hope that the gentlemen appointed by the governors will hold the scale. Otherwise it would have been better to simply have a committee nominated by the committee of selection without reference to the Board of Management.

Mr Wigan: I should like to know whether the Board are prepared to nominate three members to-day. I might say that our committee are prepared to do so and I hope the medical staff will be prepared also. It would be much wiser if the Board were in that position.

The Chairman: The Board are not in a position to nominate their members to-day. Next Tuesday, after their meeting, they will be in [illegible] with hospital matters as a [illegible] tal and upon the matters [illegible] o what he means, but it [illegible] n of the committee will be satisfactory.

Mr. Melvill Green. I did not draw the attention of the governors to one fact. The motion [illegible] governors" and [illegible] o gentlemen on [illegible] ld be very com- [illegible] on as it has been moved. I came here and I have learnt a good deal to-day, but I do not feel competent to choose who shall be on this committee to take charge of this hospital until it is reconstituted. Directly they are brought together the management of the hospital will be in their hands. I think it a wise course, which I hope they will follow, to utilise the existing management until some fresh constitution has been accepted by the governors. I hope the governors will not be called upon either to nominate or to appoint persons. I do not feel that they are competent to judge who are the best people to put on the committee.

The motion in its amended form was then put to the meeting and carried unanimously.

Mr. Wigan: I think before we separate, even if the Board are not disposed to nominate their members, we are, and I think the medical staff also, so that we shall not be the cause of the delay. As everyone will shortly be going out of town it seems to me a great mistake not to decide the matter now.

Sir John Paget: Mr. [illegible] men to fill the posts for [illegible] are also ready with the n [illegible] not. Although the Bo [illegible] meeting I sug [illegible] the names of [illegible]

Mr. Melvi [illegible] give the name [illegible] tion? (Loud [illegible] the signatories to the report, Mr. Power, who has acted as secretary, Mr. James Wigan, and myself.

Dr. Bastian. The medical staff have appointed Dr. Ormerod and Sir Felix Semon.

Mr. Wigan. I strongly urge the Board to make up their mind.

The Chairman The Board nominate Mr. Campbell, Mr. George Russell, and myself as members of the committee.

Mr. Melvill Green: We have done all we can do to-day. I will conclude by expressing our thanks to the chairman for the way in which he has performed his duties.

This was seconded by Dr. Bastian and carried.

The Chairman. I only wish that we had had a more satisfactory [illegible] ult will be satisfactory to [illegible]

De[illegible]

Ha[illegible]

Kn[illegible]

Purchas.—On July 6th, Thomas Beswick Purchas, M.D., Dep.-Insp.-Gen. R.N., aged 76 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE MART FOR BEAUTY.

It was James Thomson, the poet of "The Seasons," who remarked that "Loveliness needs not the foreign aid of ornament, but is when unadorned adorned the most." A study of the advertisement columns of the *Morning Post* for July 10th shows that loveliness if guiltless of ornament can apparently only be won by a great deal of trouble and a large expenditure of money. Is a lady too fat, then let her use Slenderine, which never causes irritation even if used to reduce a double chin. Mrs. Delia P. Watson has proof of the accuracy of this statement in her possession. Or she may consult Miss Johnson who desires to draw special attention to the new Zobeide treatment for obesity, hip reduction a special feature. The freaks of fashion are past understanding, for last year, if we remember rightly, or the year before, every woman with any pretensions to beauty wore artificial hips of portentous size. Should either of these treatments fail the too-stout sufferer can try anti-obesity pastilles, to be obtained from Mrs. Barry; or, again, Mrs. Gallop will reduce her five or six pounds weekly. Let us now consider the case of women who are thin and wrinkled. Madam Adair has introduced a wonderful Eastern oil which, according to Mrs. Deborah Primrose, fills up hollows, makes the skin smooth and white, removes all sorts of lines, while the skin tonic removes puffiness under the eyes. Its cost, we note, is but small—£1 10*s*. 6*d*. per bottle, or a sample for 10*s*. 6*d*. We gather, however, that this wonderful oil does not always succeed, for Madame (with an *e* this time) has another card to play. Wrinkles, she points out, are absolutely removed by the new Strapping Massage. Finally, we come to a lady who goes in for no half measures. Matthews Duncan used to say, "If you don't believe in yourself nobody else will," and the lady in question has evidently heard this saying, for we read: "Sister Hope Raymond (late of a well-known London hospital). New Scientific Treatment Daily: Unfailing remedy for all diseases; recommended by the medical profession."

We do not suppose that any of the above treatments would do any actual harm, and if anyone is fool enough to pay one and a half guineas for a bottle of oil the cost price of which is probably one and a half shillings or less, let them do it. But they may all do potential harm by preventing people from seeking skilled advice and the advertisements are misleading. But of Sister Hope Raymond's statement we can only say one thing—it is a lie. There is no such thing as an unfailing remedy for all diseases, neither has one been recommended by the medical profession. Quacks will continue to flourish so long as there are fools who go to them, but it is sad to see the columns of a respectable journal such as the *Morning Post* given up to spreading such trash abroad.

EXPENSES AT CARLSBAD AND HOMBURG.

To the Editors of The Lancet.

Sirs,—Could you inform me through the medium of The Lancet the probable cost of one month's stay at Carlsbad or Homburg for a bachelor in August or September?

I am, Sirs, yours faithfully,

July 5th, 1901. L.R.C.P. Edin.

*** The question is somewhat difficult to answer, as expenses depend so much upon the kind of accommodation. We should think, however, that from 12*s*. to 24*s*. per diem would cover expenses. But our correspondent had better write to some of the hotels and ask.—Ed. L.

THE FREAKS OF MEMORY.

To the Editors of The Lancet.

Sirs,—The following appeared some time ago in the *Standard*. A sailor, speaking French and Portuguese, had an accident to his head which caused him entirely to lose the faculty of speech. Unable to continue his work as a sailor, he got work to do at a market gardener's not far from Portsmouth and remained with this man for 15 years. One day when he had been near the guns when practising was going on and the noise had been great and sudden he regained his speech, but could speak *only* English, having completely forgotten both French and Portuguese. Perhaps you may have had a note of this case, or if not if you will be good enough to insert this in your journal one of your readers may be able to substantiate the case and perhaps to direct me where I could find further details.—I am, Sirs, yours faithfully,

Zurich, July 7th, 1901. A. Pariss.

"MEDICAL TESTIMONIALS."

To the Editors of The Lancet.

Sirs,—I note that your attention has been called to a circular issued by the Quadrant Cycle Company containing a letter from me together with my name. I wish you to know that on learning that this circular had been issued I at once requested the Quadrant Company to withdraw it, and explained to them that the use of a medical man's name is contrary to professional custom. They wrote me: "We hasten to express to you our deep regret that we should have infringed, unknowingly, the etiquette of the medical profession by the publication of your testimonial in the form in which it appears. ...... The fact that the circular is addressed by us to medical men shows how unconscious we were of any breach of professional usage." It appears that the company understood from their local representative that I had given him verbal permission to use my letter as a testimonial. In this, however, they were misinformed, as what I really said was that I had no objection to my letter being used *provided that my name did not appear*. I blame the company for using my name without writing for permission to do so, which would, of course, have been refused. I also blame myself for sending the letter without at the same time stating in writing that my name must not be used.

I am, Sirs yours faithfully,

July 8th, 1901. W. E. Fothergill.

PS.—At my request by telegram the editor of the *C. T. C. Gazette* wired instructions to the printer to remove my name, &c., from the Quadrant advertisement in the *Gazette* for July. He was, however, too late, the advertisement sheets having been printed already. An explanation of the mistake will be sent for publication in the next number of the *Gazette*.—W. E. F.

"HOMES FOR INEBRIATES."

The Principal of Tower House, Westgate-on-Sea, informs "Phenad" that such an arrangement as he suggests might be made with the authorities of the same. He invites particulars.

"THE TREATMENT OF ACNE."

To the Editors of The Lancet.

Sirs,—In reply to your correspondent "Acne" in The Lancet of July 6th, p. 63, who desires the best treatment for acne, I think if he will carefully consider the items of his diet he may find the cause lying therein, and he ought immediately to abstain from the "food" which to him may be a "poison." Examples of this are well known in such things as tomatoes, crayfish, gooseberries, vinegar, highly seasoned dishes, &c. Meanwhile, let him put himself on a course of the following medicine, taking particular care that it is taken on an "almost empty" stomach before meals: four grains of sulphate of iron, from a half to one drachm of sulphate of magnesia, 10 minims of dilute sulphuric acid, 10 minims of tincture of ginger, five minims of glycerine of carbolic acid, and one ounce of chloroform water. Two tablespoonfuls twice a day to be taken on an almost empty stomach one hour before meals (i.e., at 12 noon and 4 P.M. if he breakfasts at 9 A.M. and has luncheon at 1 P.M.).

I am, Sirs, yours faithfully,

A. Alison Bradburne.

"ANTI-RHEUMATIC RINGS."

To the Editors of The Lancet.

Sirs,—I am assailed on all sides with the wonders these magic rings produce. Has any reader of your paper been curious enough to analyse the yellow substance that is stated to be deposited at *only* certain periods beneath the ring, and has also the composition of the ring been examined? I have always maintained that the ring was iron and the deposit rust. Not having been enterprising enough to analyse the substances myself I should be glad to learn if this is so, as I want to be able to pulverise those people who fondly imagine that of all things the deposit is uric acid. I am, Sirs, yours faithfully,

July 2nd, 1901. M.D.

*** Our correspondent will find an analysis of an "anti-rheumatic ring" given in The Lancet of March 2nd, 1901, page 676.—Ed. L.

◆

J. L.—No. 1 Radam Microbe Killer contained 0·072 gramme free sulphur dioxide in 100 cubic centimetres, also 0·045 gramme salts and 0·5 gramme sulphuric acid. The rest was water. Radam's Microbe Killer No. 2 contained 0·07 gramme free sulphur dioxide, 0·03 gram salts, and 0·60 gramme sulphuric acid in 100 cubic centimetres. The rest was water. It is probable that both these liquids were originally stronger in sulphur dioxide, which to some extent has disappeared in favour of sulphuric acid, its oxidation product. As our correspondent knows, sulphur dioxide is a strong antiseptic and bleaching agent, and according to some authorities has been used with success as an anti-fermentative in dyspepsia.

M.D. has not stated the case with sufficient clearness. We cannot understand what position B held towards A. The whole matter, however, appears to be very small and it would be a great pity to allow any disagreement between professional colleagues to arise from it. As there is much to be said for both views why should not the fee be halved?

Clara.—The proceeding may have had some permanent effect. This, however, is not likely. The question is one that may well be put to our correspondent's family medical man.

Communications not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*Bristol Mercury, Liverpool Daily Post, Yorkshire Post, Hertfordshire Mercury, Mining Journal, Windsor and Eton Express, South African News, Leeds Mercury, Reading Mercury, Surrey Advertiser North Wales Chronicle, Weekly Free Press* (*Aberdeen*), &c.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (15th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M.).

TUESDAY (16th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

WEDNESDAY (17th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.).

THURSDAY (18th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

FRIDAY (19th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

SATURDAY (20th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.), Throat, Golden-square (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEDNESDAY (17th).—HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. Latham: Cardiac Pain.

LONDON HOSPITAL MEDICAL COLLEGE (Anatomical Theatre of the College).—4 P.M. Mr. Jonathan Hutchinson: Fatty Tumours and General Adiposity.

THURSDAY (18th).—THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Mr. Lister: Demonstration of Ophthalmic Cases.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1901, which was completed with the issue of June 29th, and the Title-page to the Volume, were given in THE LANCET of July 6th.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1901 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates on this or any other ground should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Communications, Letters, &c., have been received from—

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

Clinical Lectures

ON

THE PATHOLOGY OF HYSTERIA.

Delivered at the West End Hospital for Diseases of the Nervous System, Welbeck-street, W.,

BY THOMAS D. SAVILL, M.D. LOND.,

PHYSICIAN TO THE HOSPITAL.

I.—HYSTERICAL ATTACKS.

GENTLEMEN,—At one of our previous meetings I drew your attention to some of the important consequences which may result from disturbances of the vaso-motor and sympathetic systems,[1] and I promised to return to the subject on a future occasion. That promise I propose to redeem to-day, *apropos* of the pathology of that strange and protean disorder hysteria. The two most striking and most constant clinical features of hysterical disorders which affect the nervous system—hysterical paralysis for instance—are first, the remarkable similarity there is between the latter and a corresponding paralysis due to organic disease; and secondly, the suddenness with which the paralysis (or other malady) may appear in a person to all appearance in perfect health, and the equally sudden way in which it may disappear, without rhyme or reason, and without leaving any trace behind it.

The first of these features, the resemblance to organic disease, is often so great that it may give rise to very considerable difficulty in diagnosis. This resemblance, or mimicry as it has been thought to be by some, is so marked that one of the greatest clinical observers of the last century, Sir James Paget,[2] suggested that the prefix "neuromimetic" should be used for these cases instead of hysterical—e.g., neuromimetic paralysis, neuromimetic joint-disease, and so on. That these affections should be due to mimicry is not an idea which can for one moment be maintained, and I hardly think that Sir James Paget could have intended to use this adjective in the strictly etymological sense. It would endow the patient with a very vast and accurate anatomical knowledge and an infinitude of cunning. There is, in short, only one tenable explanation—viz, that the *same anatomical part* of the nervous system is the seat of some kind of damage, some lesion which is sudden in its onset and equally sudden in its disappearance.

It was the second of these features which led me to what I believe to be the true nature of the lesion. The sudden onset of paralysis always suggests a vascular lesion, and in point of fact the anatomical change is, in my view, a vascular one (at least so far as concerns the manifestations due to lesions of the central nervous system; as regards other hysterical disorders I shall have more to say by and by), a sudden dilatation or contraction, as the case may be, of the arterioles of a given area, accompanied in some instances by exudation, or, at any rate, disturbance of nutrition in that part of the nervous system the function of which is deranged. Just as subjects of the hysterical diathesis are liable to attacks of flushing or pallor of the skin, so also, in my belief, are they liable to attacks of flushing or pallor of various parts of the interior of the body.

To establish the truth of a proposition like this, the ordinary experimental methods of the laboratory are not applicable, for we cannot [illegible] nor are ordinary anatomical [illegible]s rarely or never die from [illegible]ore have recourse to purely clinical methods, and see how the many and varied phenomena of hysteria tally with this hypothesis, and then employ the method of analogy. I will ask your attention, first, to a case of hysterical syncope presenting some of the data on which my theory is based; secondly, to the evidences of the hysterical diathesis; and thirdly, to the causes of hysteria. We shall then, I hope, be in a position to take a broad general view of the whole subject, and on a future occasion I will ask you to study with me a complete list of hysterical disorders, the features which they present in common, and their explanations. To-day I propose to confine myself to the pathology of hysterical "attacks" or seizures, as exemplified by hysterical syncope.

The patient who will shortly come before you is suffering from an extremely common complaint, but a close scrutiny of her case will, I believe, afford us some most instructive lessons. This young woman is now 22 years of age and she has been subject, ever since puberty, to "fainting attacks" of greater or less severity, sometimes as often as two or three times a week, the frequency depending to some extent on the presence or absence of a determining cause. The attacks are always more frequent and severe about the menstrual period, when they may last for an hour; at other times they may last for only a few moments. The face and limbs become pale, and if we could see it probably the rest of the surface of the body also, and then with a sigh she sinks back, sometimes becoming completely unconscious and sometimes only partially. After a short time the surface again becomes pink and she gradually resumes her normal condition. The process of recovery, she tells us, is often attended by "a rumbling" in the abdomen and sometimes by the eructation of wind. These attacks sometimes come on without *apparent* reason, but they are far oftener determined by some trivial cause, such as an emotional upset or something which startles her. She presents the phenomenon of "ovarian tenderness" in its complete form, which I shall shortly describe to you, and firm pressure in the inguinal region very often produces a fainting attack. She spontaneously informs us that after the attacks she invariably passes a large quantity of almost colourless urine—an occurrence frequently met with in such cases. She has derived much benefit from static electricity, and, for the attacks, assafœtida.

This is a very typical case of hysterical syncope, and I want you to observe that the most interesting clinical features of these "nervous faints," all of which are present in this patient, are as follows. 1. That whereas the great majority of persons never faint, such attacks are liable to occur many times during the lifetime of certain individuals, on more or less provocation. There may be very many years' interval between the attacks, but one of the means of diagnosing the condition is a history of its previous occurrence. In other words, there seems to be an inherent, innate, or inherited quality in some part of the nervous or neuro-vascular system of these persons which does not exist in other people. 2. The sufferers from these attacks are almost always of the female sex. 3. The determining cause of an attack is very frequently of an emotional kind, such as fear, grief, fright, and the like, or some kind of shock. 4 On inquiry, it will generally be found that these same subjects are liable, on the occurrence of the same causes which produce the "faints," to flushes or flush-storms, and perhaps to one or other of the many various forms of hysterical attack which I shall mention shortly, and that these flushes and the other seizures are interchangeable with one another and with the "faints." For instance, another patient now under my care, aged 27 years, is liable at all times to flushings, but the same causes which determine these will, at the catamenial period, result in syncopal attacks. 5 Pallor of the surface marks the initial stage, and lasts during the attack. This is almost certainly due to vaso-motor disturbance—that is to say, a contraction of the surface vessels, which may be primary or secondary to dilatation of the internal vessels, e.g., the arterioles of the splanchnic area. Some suggest that it is due to cardiac failure, but that the other explanation is the more probable, and that the pallor of the surface is secondary to dilatation of the internal vessels, is rendered far more likely by consideration of my next point. 6. Copious urination of pale, highly watery urine follows these syncopal attacks, and this seems to indicate that there has been during the faint a corresponding dilatation of the arterioles of the splanchnic area. This same copious flow of watery urine follows other hysterical seizures, and we have here a very important clue to their pathology. The kidney is extremely sensitive to any alteration in the blood-pressure, as Roy's experiments have shown. The secretion of the watery constituent of the urine, which largely depends on the blood-pressure in the glomeruli, may be increased by (1) any increase in the general blood-pressure such as may be produced by (*a*) increased force of the heart beat, or (*b*) constriction of the arterioles of the skin or other large vascular area; or (2) relaxation of the renal artery. No wonder, then, that there is a copious secretion of urine, for we know that there is marked constriction of the arterioles of the skin; this we can see, and there are very good reasons for believing that there is a dilatation of the splanchnic arteries which are supplied from the same sympathetic centre as the renal arteries, and therefore the latter are most probably relaxed also. 7. These (and other) attacks are very often preceded (at least according to the report of observant patients) by a curious, indefinable, but extremely disagreeable sensation in the region of "the stomach"; some patients describe it as "a throbbing," a "sinking" or "relaxed feeling" in the abdomen. The same kind of feeling, this patient tells us, may be produced by the emotions of fright, fear, or terror; moreover, very much the same kind of sensation, this patient also spontaneously tells us, may be produced by pressure in the inguinal region and may be then followed by a fainting attack.

---

[1] Vide THE LANCET, June 1st, 1901, p. 1513.

[2] Sir James Paget: Clinical Lectures and Essays, edited by Howard J. Marsh. London: Longmans, 1879.

It seems to me that sufficient attention is not always paid to the details which I have just mentioned. We now know, thanks to the researches of Dr. Leonard Hill,[3] that the blood-pressure in the cerebral arteries is very largely, if not entirely, regulated by the amount of blood in the splanchnic area, and that the arterioles of this area are capable of an enormous amount of expansion and contraction; indeed, it has been stated that they are capable of containing nearly half of the total blood in the body at one time. If therefore the splanchnic area suddenly dilates cerebral anæmia immediately results, and *vice versâ*. We know also that cerebral anæmia will produce syncope and even convulsions.[4] The inference from the foregoing facts is that the essential lesion of these nervous faints is to be sought in the abdominal sympathetic, and that this lesion, whatever it may be, gives rise to a rapid dilatation of the splanchnic arteries and consequently to cerebral anæmia.

To carry this line of argument a step further, there is very good reason to believe that the pallor of the surface which accompanies the emotion of fear is due to a similar splanchnic dilatation It seems highly probable, therefore, that the nervous apparatus of the splanchnic area—i.e., the abdominal sympathetic—in these individuals is unduly susceptible and that it is readily influenced by fright, grief, anger, and other emotional causes—emotional conditions, be it observed, which are particularly apt to be met with in hysterical persons and in the female sex.

II.—The Hysterical Diathesis.

The *hysterical diathesis* and the symptoms by which it is recognised next claim our attention. There are two objections to the use of the term "hysteria,"—one is the opprobrium attaching to it and the other is its ambiguity. Its use has been sanctioned by such long-established custom that it cannot be discarded. The term is often applied very loosely either to the inherent tendency—i.e., the diathesis—which may exist in an individual to the development of certain symptoms—paralysis, anæsthesia, syncope, convulsions, joint disease, &c., or else to those symptoms themselves.[5] The hysterical diathesis may, I believe, be defined as a peculiar condition of the nervous system, inherent in the individual and for the most part inherited, consisting in its *psychical* aspect of a want of self-control and emotional instability, and in its *physical* aspect of a tendency throughout life to the development of various sensory, motor, visceral, or neuro-vascular disturbances unconnected with any definite organic lesion discoverable by our present means of investigation. That there is an organic change I firmly believe, and the chief purpose of our studies to-day is to ascertain its probable nature and position.

Older authors used to describe a special expression of face as belonging to subjects of the hysterical diathesis, but I have never found any one type of facies uniformly attaching to the condition. The mental and physical peculiarities, however, are certainly of such a kind that, given adequate opportunity, one may, I believe, recognise them. The leading features of the *hysterical order of mind* are (1) a lack of will-power or persistence of thought and action and (2) an emotional instability. The intellect may be, but it is not necessarily, below par—a fact on which most observers are now agreed; indeed, some of the brightest and most refined intellects in history have been found amongst hysterical women, especially when they have had an incentive (such as dire necessity) to the evolution of sufficient steadiness of purpose and self-control. The will-power, I believe, may sometimes be cultivated by educated women to such an extent as to deceive the physician for a long time, and thus he may even be led to believe that he has to deal with a masculine type of woman. Sooner or later, however, it is generally by the emotional instability that we recognise the diathesis. These patients in ordinary circumstances are easily roused to violent expressions of feeling, to hasty judgments, to impulsive actions, and to passionate exhibitions of various kinds. One moment they are angry (or pleased) because a thing is going to be done; the next moment they are cross (or pleased) because it has not been done. I do not believe that the emotions are necessarily in excess, but these, like the centre controlling the splanchnic area in our patient, are unstable and hyper-sensitive. Little things affect these people because of this instability. And this leads me to refer to a subject on which I believe there is sometimes a grievous misunderstanding. I can find no real grounds for believing that the sexual desire in hysterical females is either more or less than in other persons, but the fact is this, that their normal desires are not under normal control and thus they may be led sometimes to an excess or deficiency of modesty in their demeanour. The unrestrained and ill-regulated sexual emotions of these subjects lead them sometimes to assume a bearing in the presence of the other sex which has, unfortunately, led many otherwise discriminating physicians to assume, not only that excessive sexual desire is a symptom of the diathesis, but that the gratification of it will lead to its cure. Never, I believe, was there a greater mistake. I shall have to refer to this subject again, and we must now pass to the physical evidences of the diathesis which more immediately concerns us now.

Three *physical peculiarities* have I found to be very constantly associated with the hysterical diathesis. Firstly, there is a marked tendency to "flushing," with very little, and sometimes apparently without any, provocation. These flushes occur in parts that are exposed, like the face and neck, and also in parts that are unexposed. Sometimes they take the form of an erythema or even an urticaria, usually very transient, sometimes more enduring. I have several patients now under treatment who can from time to time show me "red marks," as they call them (small localised patches of congestion), which come out "when they are nervous." They are extremely fugitive and are, I find, hardly known among physicians; indeed, the patients themselves very often overlook them for they give rise to no inconvenience unless, as in four or five cases which I have seen at the Hospital for Diseases of the Skin, they come on the face or neck, when they seek advice. For the "blushings," "flushings," and "flush-storms," to which these subjects are so liable, I would refer you to the excellent description and analysis by my colleague, Dr. Harry Campbell,[6] though they have been often observed by others,[7] and I need not dwell further upon them, except to remark that they indicate once more an instability of the various vaso-motor reflex centres.

Secondly, in a large proportion of these people the superficial and deep reflexes are slightly, though perceptibly, increased. As to the superficial reflexes it is a notorious fact that these subjects are what is called "very ticklish"—i.e., their superficial reflexes are hyper-sensitive. It is also a fact, though not so well known, that their patellar and other tendon reflexes are unduly marked. I have often called your attention to very marked instances of this.

Thirdly, there is, about all their vital phenomena, whether healthy or morbid, a variable or paroxysmal character, a change from day to day, which seems quite peculiar to them I must not dwell longer upon them, but these are the chief characteristics of the hysterical diathesis or temperament Individually these qualities may not be very distinctive, but collectively—the deficient will-power, the emotional instability, the ready flushing, the excitable reflexes, and the variability of the vital phenomena—they are so far distinctive as to enable a careful observer to recognise the condition readily enough in the female sex They may become more marked at one time than another, especially when the patient is out of health and particularly at the evolution and involution of a woman's sexual life, but I will ask you to notice that these symptoms or characteristics exist as innate qualities throughout the life of the individual who is the subject of the diathesis

[4] Kussmaul: New Sydenham's Society's publications, vol. v., 1859.

[5] The Greek word διαθεσις means a disposition or tendency, and the rheumatic, scrofulous, hæmorrhagic, or calculous diatheses severally indicate a tendency to the development of rheumatism, tubercle, hæmorrhage, or stone. These are strictly comparable to the hysterical diathesis, and one might just as well talk of tuberculous peritonitis being an attack of "struma" as to speak of hysterical syncope or convulsions being an attack of hysteria. It is too vague.

[6] "Flushing and Morbid Blushing." London, 1890.

[7] Sir James Paget remarks, "The distribution of blood is, in many of the mimic cases, greatly affected. Heat and cold of the same part, rapidly succeeding one another, flushing and pallor, turgidity and collapse—all of these are frequent, striking, and capricious in the nervous mimicries."—The Lancet, Oct. 11th, 1873, p. 512.

Sooner or later, however, generally before the age of 25 or 30 years,[8] a large proportion of these subjects exhibit some more decisive manifestation in the shape of an *hysterical disorder* Of these there are, as we shall see, an infinite variety, but there are some which are of such common occurrence in hysterical individuals that they are sometimes spoken of as hysterical stigmata, though this name ought more properly to be reserved for the five characteristics which I have just described. Certainly the most frequent of these is some kind of "nervous attack" ("*attaques des nerfs*," as they are termed in France) These may consist of syncope, as in our patient, or "emotional attacks" of crying or laughter without adequate cause ("hysterics"), or any of the other kinds to be mentioned shortly Sometimes they occur, to all appearances, spontaneously, but more often they are determined by some emotional upset, and they may in many instances be determined by pressure on the inguinal region Perhaps the next most frequent hysterical disorder is hemi-*anæsthesia, or some other perversion of sensation, or patches* of anæsthesia, the existence of which may be unknown to the patient until medical examination reveals it Thus we have discovered for the first time that our patient has several patches of anæsthesia on the legs All the other physical manifestations, and so far as can be judged the mental peculiarities, are also present in this young woman. The hysterical diathesis is strongly marked in her

III —CAUSES OF HYSTERIA

Let us now turn to the *etiology of hysteria* This patient is a typical example in this respect also Her paternal grandmother was "hysterical" and though her mother was said to have been free from any neurosis, both her parents were addicted to alcohol I want to draw a well marked distinction between the *predisposing* causes, the *contributory* or exciting causes, and the causes which may *determine* an attack. The predisposing causes are practically only two in number, Sex and Heredity The far greater liability of the female sex is so well known and admitted that this need not detain us Out of 336 cases which I have collected only 26 were males But what I want to emphasise is that the hysterical diathesis is essentially something that is inherited or inherent in the individual, and that without it both *exciting and determining* causes are, in all ordinary circumstances, unable to act This has been insisted on by many of the ablest observers such as Guinon, Charcot, and Briquet[9] There are three ways in which heredity may come into operation First, there may be a *direct* inheritance of the hysterical diathesis, and one or more of the children of an hysterical mother or grandmother—the influence is far more potent on the mother's side—are almost sure to be hysterical themselves I have shown you many instances of this Quite as frequently, however, there is an *indirect* hereditary influence in the shape of a general neuropathy This is particularly the case when insanity is present in the family history—a fact which shows once more the close relationship between hysteria and mental disorder Finally, and this is a point which has not, so far as I am aware, been sufficiently insisted upon [10] alcoholic parents, whose family may be free from any kind of neuropathic taint, will often propagate children afflicted with the hysterical diathesis. Our patient, therefore, derives the hysterical diathesis from the first and third of these sources

As regards age, undoubtedly puberty and the climacteric offer a predisposition, and our patient's troubles date from the former

Among the contributory or exciting causes are many conditions which lower the mental or bodily strength, the will-power, or the emotional stability Continuous emotional strain such as grief, repeated attempts at hypnotisation, infectious or exhausting maladies, hæmorrhages and similar conditions leading to general debility, physical or mental overwork, venereal excess, anæmia, plumbism, mercurialism, alcoholism, syphilis, pregnancy, parturition, organic diseases of the nervous system are some of the causes which I have found in operation and which are capable of exciting an outbreak of some kind of hysterical disorder But as Guinon[11] truly points out these are only contributing causes and are only capable, under ordinary circumstances, of acting "in a person predisposed by heredity and sex."

The question whether celibacy and unsatisfied sexual desire are contributory causes of hysteria is an important one, but it is not easy to settle absolutely Personally, I cannot find anything in support of this view, and I have just now mentioned what I believe to be the true explanation of the immodest bearing sometimes observed in hysterical females—namely, that their emotions and desires, though normal in amount, are not under normal self control Nevertheless, there are some observers who argue from this and other circumstances that celibacy and sexual continence are potent causes both of the hysterical diathesis and of hysterical disorders It is true that matrimony sometimes leads to a temporary disappearance of certain hysterical symptoms, but this is readily explained by the fact that the patient has newer and wider interests which take her out of herself; moreover, removal from the surroundings under which a hysterical disorder arose will often of itself lead to recovery, as I have shown you in several instances Some years ago I collected statistics which show that the incidence of hysterical phenomena was very nearly the same among married and unmarried females of the same age-periods other things being equal These data also revealed the fact that many happily married women are attacked by hysterical disorders quite as grave as their unmarried sisters I may also refer to the researches of Briquet in this matter which did not come to my notice until after I had independently arrived at the same conclusions He found on inquiry that hysteria was not more common in those religious sisterhoods where the law of celibacy was followed than amongst communities where celibacy was not observed An exhaustive inquiry into three large social classes—religious sisterhoods, domestic servants, and prostitutes—led him to the undoubted conclusion that "continence is not a cause of hysteria."[12]

The conditions of a person's environment undoubtedly influence the occurrence of hysterical manifestations and are capable of greatly promoting their cure when they have appeared This is only what one would expect in a disease so much dependent on emotional states, and a condition of affluence in which a young woman has no interest in life beyond her own health undoubtedly fosters, but it does not produce, hysteria.

Education, therefore and social position no doubt count for something in the causation of hysteria, but not as much as one would think. When I first went to the Paddington Infirmary I expected to be deprived of the field which the better classes of hospital practice afforded, but it was not so I found that hysteria was very nearly as rife among the poor and destitute as among the wage-earners and the affluent I have been at some considerable pains to ascertain the relative incidence, because it is rather a favourite dictum with some that hysteria is entirely the outcome of a lazy, self-indulgent life Supposing we divide a community into three classes (1) those in easy circumstances not obliged to work; (2) those who work for their living; and (3) those who are destitute The first might be represented by private practice, the second by hospital patients, and the third by workhouse infirmary patients I collected without selection 1000 patients from each class and found that the proportion of hysterical complaints among the first class was 67 per 1000, among the second it was 53 per 1000, while among the third it was 60 per 1000 However, I am inclined to think that faulty education combined with an absence of any necessity to earn their daily bread may act as contributory factors, and also afford the patient abundant opportunity to pay attention to the more trivial ailments which would swell the category of hysteria. These factors would tend to increase the number of cases in Class 1. On the other hand, alcoholism in the parents would tend to increase the numbers in Classes 2 and 3, so that these two considerations would tend to balance each other. It is very difficult, if not impossible, to obtain statistics on these matters which shall be free from fallacy.

---

[8] Briquet says that hysterical disorders *always* appear for the first time before the age of 30—Traité de l'Hystérie Clinique et Thérapeutique Paris: 1859

[9] Guinon: Agents Provocateurs de l'Hystérie, Charcot: Leçons sur les Maladies du Système Nerveux, Briquet: Loc. cit

[10] Charcot however frequently refers to the powerful part which alcoholism plays in the production of general neuropathic heredity

[11] Guinon: Loc cit

[12] Briquet: Loc. cit

Before concluding the subject of exciting or contributory causes of hysteria I should like, in passing, to mention a fact but little known which was first revealed by that painstaking observer Briquet, whom I have already quoted. A most exhaustive inquiry into the family histories of hysterical and non-hysterical mothers lead him to the conclusion (p. 527) that "infants, born of hysterical mothers, present a much greater fatality and die at a much younger age than those who are born of non-hysterical mothers" Possibly the former do not know how to take care of their children so well as the latter. But whatever the explanation may be, hysteria, being so largely an hereditary complaint, ought in the course of many generations to die out from amongst us. In point of fact, if one can rely on ancient records[13] the cases which are met with in the present day are in general terms less severe than formerly. We have no means of ascertaining exact facts as to frequency, but I fear that alcoholism in the parents, being such a perennial source, would counterbalance any diminution of the disease in the process of evolution.

It now only remains for us to consider the third group of causes—namely, those which actually *determine* a paroxysm or attack of some hysterical symptom—severe enough, perhaps, while they last, but usually transient, such as syncope, catalepsy, convulsions, somnolence, &c. The manifold ways in which this may be brought about are doubtless so familiar to you that I need not dwell upon them. Practically these can nearly always be traced to some emotional disturbance or instability. Some of you may remember the case of the woman whose symptoms dated from a cataleptic seizure which supervened after going to the theatre to see a performance of "The Sign of the Cross" I have shown you from time to time many illustrations of how anger, grief, fear, joy, traumatism (i.e., fright), &c., may act in this way. But this cause, like the last group, is powerless unless a predisposition (i.e., the diathesis) exists. Moreover, the degree of emotional disturbance necessary to produce an attack varies inversely with the degree of the predisposition present in the patient. In the patient whom you have just seen the predisposition is fairly marked, and when to this is added the exciting condition of the menstrual period the determining cause necessary was so slight that it would escape notice and the "faints" appeared to come on almost spontaneously. In one of the patients I saw in the late Professor Charcot's clinique in 1888, the slamming of a door was sufficient to determine a cataleptic seizure; and the patient, a girl, 17 years of age, would remain rigidly fixed in whatever position she happened to be at that moment, until someone who knew the secret came and pressed on one of her numerous hysterogenic zones and released her from her uncomfortable position.

IV.—PATHOLOGY OF THE HYSTEROGENIC PHENOMENON.

There is still one determining cause of these attacks which deserves our very careful consideration. Hysterical attacks differ from all other kinds of seizure in one very remarkable way—viz., that they can be produced in a large number of instances at will by pressing firmly and steadily on some part of the patient's body, usually the inguinal region. In our patient you have seen that pressure on the inguinal region on either side produced either a complete syncopal attack or the same disagreeable sensations which formed its initial stage, and which are collectively known as the "aura" It produces, she says, a feeling of "painful suffocation" or the "sinking in the stomach like you get on the switchback railway, only worse." This sensation then rapidly rises up from the groin and the abdomen towards the chest and throat and terminates in the feeling as of a ball in the throat (globus hystericus). Sometimes the bystanders can hear the patient make a gurgling attempt to swallow "the ball." In other subjects pressure in this region produces sighing and a feeling of "faintness and sinking in the abdomen." The series of sensations so produced is generally called in England "ovarian tenderness," but nothing could be more misleading. It has not the slightest resemblance to the tendernes which you or I feel when pressure is exerted in this region. It is best to call it as the French do, the "*ovarie*," or better, perhaps, the "inguinal or hysterogenic phenomenon," for it may exist, as I have shown you, in a very complete form in hysterical males. It only exists, in my experience, when the patient is, or has been, the subject of some form of h terical attack. It may thus terminate in rigidity of t limbs (one man whom I showed you assumed the position o opisthotonos), or tremor, catalepsy, or convulsions, local o general. The points, pressure upon which will produce the sensations just described, are called in France "hysterogenic zones," and though the inguinal region is the most frequent, the submammary region is another situation, and altogether there may be, in some cases, a score of hysterogenic zones, in different parts of the trunk; never on the limbs.[14] In some patients in whom a number of such zones exist pressure upon one of the will produce an attack, while pressure upon another point or a second pressure upon the same point, will stop it. Some of you will remember my showing you a young woman (a patient under the care of my colleague Dr. T. Outterson Wood) in whom pressure on the submammary region produced a violent attack of clonic spasms of the head and neck, while pressure on the ovarian region stopped them—a fact of which the patient and her friends were not slow avail themselves, for these spasms when unchecked were great violence and caused the perspiration to drip from he forehead.

Gentlemen, if these phenomena have anything to do with the ovary, how is it that they occur in the male, for undoubtedly they do, and in a very marked manner? Nor are they connected with the testicle apparently, for in male hysterical subjects this organ is only very occasionally the seat of "ovarian tenderness," and then in all the cases I have seen *this organ has been undescended*. By far the commo position of hysterogenic zone in male patients is the ingui region, the region which is supplied by the ilio-hypogast (and sometimes, less or more in different subjects, by the ili inguinal) nerve. This nerve is entirely cutaneous or centri petal. It starts from the skin over the buttock and the skin in the inguinal region, and passing into the abdominal cavity it joins the first lumbar nerve-trunk, where it comes into very intimate relation with the solar plexus, the largest mass of sympathetic ganglia and fibres, not only in the abdomen, but in the body.

We have seen good reasons for believing that attacks such as those in this patient are due to the sudden dilatation of the abdominal vessels, and if this line of reasoning be corre we can now understand how it is that pressure in th inguinal region may produce the aura and all the succeeding phenomena of an attack. The ilio-hypogastric nerve is apparently the centripetal depressor nerve of the abdominal sympathetic, and irritation of it by pressure in this region produces dilatation of the splanchnic area and consequently cerebral anæmia. There may, apparently, be other depressor nerves in patients who present other hysterogenic zones.

This explains many of the strange and apparently inconsistent features of these and other hysterical attacks, if we look upon the splanchnic area as the point whence they start. And thus we see that the abdominal sympathetic may be influenced (*a*) through the ilio-hypogastric nerve (or the nerve from some other hysterogenic zone) or (*b*) through the brain by some emotional influence. There is nothing new or strange in the emotions influencing the sympathetic nerves. Does not the sight of food induce secretion of gastric juice? I shall submit further proofs at our next meeting. Moreover, we can now understand how it is that these attack can be produced, or at any rate, aggravated, by (*c*) flatulent distension of the bowel—i.e., by irritation of other centripetal branches of the abdominal sympathetic. Have you not often heard the patient's friends remark: "Directly she brings up the wind she gets better" (it was so in the case before you), and that is, no doubt, why anti-spasmodic remedies such as assafœtida, valerian, or even peppermint, will often give speedy relief. There are no doubt other centi petal tracts, but I must defer these until our next meeting.

---

[13] See numerous contributions by Dr. Henri Miege in the Nouvelle Iconographie de la Salpêtrière; and also a separate work by Professor Charcot, "Les Démoniaques dans l'Art."

[14] In very rare instances they may occur on the upper or lower extremities. Thus M. Gaube (Recherches sur les Zones Hystérogènes, Thèse de Bordeaux, 1882) mentions a case of that kind.

SOME FURTHER CASES OF ETHYL CHLORIDE NARCOSIS

BY W J McCARDIE B A, M B, B C CANTAB,
ANÆSTHETIST TO THE GENERAL AND DENTAL HOSPITALS BIRMINGHAM

THERE was recently published in THE LANCET[1] a paper in which I gave short notes of some cases of ethyl chloride narcosis and I am now recounting my experience of some more cases in the hope that it may be a help to others who wish to make trial of ethyl chloride as a general anæsthetic One case is of interest because the patient died about an hour after the administration, another case because of the development of a rash (which I had not previously seen described as following the use of the drug) during anæsthesia, and yet another case because the accompanying muscular excitement made full anæsthesia and operation impossible The longest operative anæsthesia lasted for from 16 to 17 minutes and the result in every way was excellent although according to her medical attendant, the patient had had very serious symptoms when he had once before given her chloroform. The administrations for removal of tonsils and adenoids in many of the selected cases gave excellent results A study of the subjoined list of cases both successes and failures, will best give an idea of the possibilities of ethyl chloride.

CASE 1 *Operation for abscess of the leg scraping &c* —The patient was a boy, six years old He was pale but had no cough The chest was not examined The patient was prepared for operation and took about one minute to go under anæsthesia The reflex was not lost As the Breuer's inhaler, which was used was too large it was difficult to keep level anæsthesia and as I gave too little of the drug the patient at intervals cried and moved. His respiration when properly under anæsthesia was regular His colour was always good and his pupils were of moderate size There were no after effects and the patient remembered nothing The operative anæsthesia was five minutes The lad awoke too soon to consciousness of pain if he had had chloroform or ether he might have slept all night instead of crying during most of it

CASE 2. *Amputation of the finger* —The patient was a girl six years of age, a bonny rosy child The chest was not examined She was prepared for operation and the course of the anæsthesia was much the same as in Case 1 The patient only phonated two or three times during the operation There was a moderate amount of mucus, the colour was heightened throughout The child made a perfect recovery and remembered nothing afterwards The induction of anæsthesia took one and a half minutes The operative anæsthesia was over five minutes The patient was quite well afterwards and ate a good meal in half an hour after the operation

CASE 3 *Suppurating bursa patellæ* —The patient was a woman, aged 35 years The case was of an ordinary type The chest examination revealed nothing. She was prepared for operation and was under anæsthesia in two minutes She had a very good colour throughout but there was slight phonation at times There was nearly always a brisk reflex this was only once abolished There was always very slight rigidity which was not, however inconvenient When phonating the pulse was rather quick otherwise it was about normal Respiration was always good and vigorous The pupils were moderately or well contracted When the dressings were being applied the patient cried out that she was being hurt, but she afterwards declared that she felt and remembered nothing Recovery took place in less than one minute The operative anæsthesia was fully four and a half minutes From eight to 10 cubic centimetres were used in three or four doses This was a very satisfactory case The patient had pleasant and peculiar dreams which she would not tell

CASE 4 *Perineal abscess* —The patient was a strong man aged 28 years He was prepared for an anæsthetic He was put in the lithotomy position and went under anæsthesia quietly In two minutes the conjunctival reflex was very dull and the operation was begun There was a very slight, but not inconvenient, rigidity, with little movement of the legs The breathing was regular and vigorous the colour was good, and the pupils were moderately or well contracted throughout Altogether 14 or 15 cubic centimetres were used in three or four doses Rapid recovery ensued in less than one minute There were no after effects, the patient talking as he was being wheeled away He was very pleased with the effects of the "gas" as he called it The operative anæsthesia was about four and a half minutes There was a large remainder of ethyl chloride on the inhaler

CASE 5 *Exploring a lump in the axilla* —The patient was a youth, aged 15 years, who showed a good deal of malaise but was otherwise healthy and sturdy He was placed in bed and there was no preparation for the anæsthetic Five cubic centimetres were poured on for the first dose The patient breathed quietly and deeply and was under anæsthesia in one minute The reflex was very much dulled when the incision was made and there was no movement The pupils were well contracted and there were heightened colour and vigorous respiration throughout, also slight conjunctival reflex The operative anæsthesia was over in four minutes There was perfect recovery, in less than one minute the patient was talking rationally He was sick once about an hour afterwards this was probably due to malaise

CASE 6 *Scraping gland and skin of the neck* —The patient was a boy, aged six years quiet and ill developed. The chest was not examined He was prepared for operation There was quiet induction in less than one minute There was just the slightest movement on first scraping but none after The reflex was just abolished once The pupils were always of moderate size the colour was rather flushed There were perfect anæsthesia and rapid recovery with vomiting of half an ounce of yellow bilious fluid The boy was conscious in less than one minute and he gladly accepted a small coin There were no after effects but he was very soon hungry The operative anæsthesia was just three minutes After the operation had commenced a patchy and erythematous rash was found on the upper part of the chest and the arms, especially on the left side, one or two of the patches being as large as the palm of the hand The rash disappeared in three minutes after the boy's return to the ward altogether lasting about 10 minutes There was no rash before the operation and there was nothing to distinguish this erythema from that sometimes occurring during etherisation

CASE 7 *Circumcision* —The patient was a boy, aged 11 years Some degree of paraplegia and ataxia were present. The boy was ill developed, his chest was not examined The patient was prepared for operation as usual At first he cried a little then he breathed quietly and was anæsthetic—i e, the limbs were relaxed and the conjunctival reflex was dulled—in about one minute Section of the prepuce caused no reaction About a minute later I allowed him to recover too brisk a reflex and he began to move his arms and legs and phonated very slightly The operation was uninterrupted and movement soon stopped Thereafter I kept up a deeper and an even narcosis the lid reflex being quite or nearly abolished The colour was heightened throughout The pupils were always well contracted I did not myself feel the pulse but the house physician who stood by said that it was of good volume though low in tension To relieve the patient of the pain which would otherwise have been caused by the nature of the dressing which was gauze and collodion I kept up the administration until the dressings had been applied In about half a minute from the removal of the mask he began to retch and to vomit, becoming a little blue After however, bringing up some bilious fluid and mucus he regained consciousness Later, he felt a little sick for about an hour, his chief complaint was the wound pain The operative narcosis lasted from 10 to 11 minutes

CASE 8 *Extensive cellulitis of the hand, extending to the wrist-joint* —The patient a woman, aged 60 years, had had, I was told chloroform some time before with very serious complications during administration She was a spare woman but her general condition was fair There was no cough She was very nervous and had been prepared for operation. There was nothing special in the chest She took the anæsthetic very well breathing regularly and quietly and there was no excitement She was under anæsthesia in two minutes the dressings being removed after the first minute There was slight but not inconvenient movement of the limbs at first, which was easily restrained by the nurse After three minutes' exploration and incisions there were slight movements of the legs and phonation, the latter recurring two or three times during the operation and disappearing with more of the drug. The head was easily kept on one side. There was no mucus. The patient's general condition all through the operation was excellent—in fact, there appeared to be a distinct degree of stimulation. The breathing was regular and rather rapid, and on an average 45 to the minute. The pulse was regular and full and rather more rapid than before the administration, and was certainly of better quality. The colour of the face, the lips, and the ears, and the vascular reflex thereof were excellent. Generally during the administration there was strong contraction of the muscles closing the eyes, which it would have needed a good deal more, and an unnecessary amount, of the drug to abolish. The pupils were of moderate size or well contracted. A deeper degree of anæsthesia, though characterised generally as above, caused, in addition, full muscular relaxation and deeper breathing. Administration was only stopped when all the dressings had been applied. The patient quietly came round in about two minutes, being in an analgetic, sleep-like state during the recovery. There was no after-effect whatsoever. The patient had a good meal of milk one and a quarter hours after the operation and enjoyed it. The operative anæsthesia lasted for from 16 to 17 minutes. The quantity of ethyl chloride used was 35 cubic centimetres given in small doses of from three to five cubic centimetres; probably about 30 cubic centimetres were inhaled, some being left over on the gauze. In other circumstances I should have given gas and oxygen to this patient. Though she had had chloroform some time ago, and had, according to her medical attendant, been in serious danger therefrom, ethyl chloride had a favourable influence. Her general condition during administration somewhat reminded me of that which exists under the A.C.E. mixture except for the absence of mucus and presence of reflexes and slight rigidity, in that the drug appeared to have a somewhat stimulating effect. If in cases like these ethyl chloride can be relied on it would appear better to fill the gap occupied by gas and oxygen than this mixture itself, as the apparatus which is needed is so simple and portable, while there is not the difficulty of supplying oxygen artificially. I should have had no hesitation in prolonging the administration for half an hour or so had it been necessary.

---

[1] THE LANCET March 9th 1901 p 698

CASE 9. *Internal urethrotomy and sounding, &c.*—The patient was a man, aged 37 years, spare and excessively nervous; he had the staring eyes and facies of a man in a terrible fright. He had been a hard spirit-drinker for several years and had not been sober for months before his admission into the hospital. He was in an extremely bad general condition. He had had hæmaturia shortly before and then had retention of urine. On the previous night one of the house surgeons tried to give him gas, but could not put him under anæsthesia, as he struggled and fought, and nothing was done. His pupils were large. Nothing special was found in front of the chest. His complexion was earthy, his pulse was weak and quick, and there was pus in the urine. Serious kidney lesion was diagnosed. The administration was begun in the anæsthetic room. The patient took the anæsthetic fairly quietly, and in two minutes, while he still had a reflex, he was wheeled into the operating room and placed on the table. At the fourth minute an attempt was made to introduce the catheter but he moved his legs too much; this, however, was easily restrained by the nurse, and in another minute the operation proceeded and the patient's movements became less. There were vigorous respiration, improved colour, strong conjunctival reflex, moderate-sized pupils, and fair pulse throughout, the drug appearing to act as a stimulant. Full recovery occurred in from one minute to one and a half minutes, the patient appearing at first dazed and excited. The operative anæsthesia was seven minutes. A few cubic centimetres were administered at a time and the gauze was kept constantly frozen. Anæsthesia, though light, was perfect and I should have had no hesitation in continuing the administration for a much longer time if necessary. About 20 cubic centimetres were used. On his return to the ward the patient was quite conscious and rational, complaining of nothing but pain on micturition. He would not eat his full dinner but took a fair quantity of milk half an hour after the operation. The pulse was frequently felt by the nurse after the operation, though no danger or trouble was anticipated; it was, she said, of fair quality and never more than 90 or 94. The colour was as good as before the operation. The patient lay quietly all the time recumbent in bed. His bowels were moved four times, a little blood appearing in one stool, probably from the urethra. He had one slight but distinct rigor. During the last motion he was calling out with pain, and when in a minute or two the nurse went to him he was dead. This happened about one and a quarter hours after his return to the ward. A post-mortem examination was made on March 30th by Dr. J. G. Emanuel, pathologist to the General Hospital. The diagnosis was meatal stricture, consecutive nephritis, adhesive peritonitis, pericarditis, pleuritis, and fatty liver. The body was well developed and well nourished. Rigor mortis was present. The heart weighed 11½ ounces. The pericardial cavity was quite obliterated. The layers were closely adherent but separable by manipulation; there was no thickening of either layer and no hypertrophy of the heart. There were a little dilatation of the left ventricle and a few sub-pericardial and sub-endothelial ecchymoses; the cardiac muscle was fairly firm. The right lung weighed 20 ounces and the left 17 ounces. There were a few old adhesions in each pleural cavity. Both lungs were crepitant. The peritoneum was the seat of chronic adhesive peritonitis throughout. There was no ascites; all the coils of the intestines were glued together in much the same way as the pericardium. The peritoneum over the liver, the spleen, and the bladder was in the same condition. There were no enlarged mesenteric glands. The appendix was healthy and there were no signs of tubercle. The liver weighed 68 ounces; it was large, soft, and fatty. The pancreas was healthy. The right kidney weighed eight ounces and the left 11 ounces, the right kidney being large and healthy and the left very large and markedly congested, containing in the cortex and medulla three or four small (pinhead) pyæmic abscesses. The capsules stripped easily. There was no diminution of cortex and the texture was generally normal in both organs. The bladder was dilated, there were chronic cystitis and a few sub-mucous ecchymoses. The urethra was the seat of a long fibrous stricture situated in the body of the organ. The suprarenals were healthy. The spleen was large, diffluent, and septic-looking. The brain was normal; it weighed 47 ounces. Death in this case was probably not due to ethyl chloride for the following reasons: 1. Because all of the very volatile drug had been eliminated an hour before death as was shown by the rapid and perfect recovery, absence of other after-effects, and capacity to take food. 2. Because death could be more easily explained by the bad condition of the heart and other organs, affected secondarily, perhaps, by the straining and rigor. Death occurred evidently from heart failure. 3. If death was due to ethyl chloride the patient would more likely have died during administration or recovery from it. I should not have cared to have administered chloroform and the other alternative anæsthetic would have been ether. Seitz records a case of syncope during recovery—i.e., while the drug was still in the lungs and circulation. Besides a death recorded by Lotheissen as having occurred during administration in a bad subject, another one is reported by Zeitz[2] of Zürich as happening 16 hours after operation to a patient in bad condition and who had kyphoscoliosis. Two grammes of ethyl chloride had been used for a tooth extraction and immediately afterwards respiration stopped. The patient temporarily recovered after the application of resuscitative measures but died later as related.

CASE 10. *Opening and scraping of an abscess of the foot.*—The patient was a stout, rosy-cheeked girl, aged six years. She was prepared for operation. She had a little cough. The nasal airway was obstructed and the mouth was open; the patient probably had adenoids. An examination of the chest revealed nothing. The administration was begun with one or two cubic centimetres at a time; there was no trouble. After one minute the cleaning operation was begun, causing only a little leg movement and slight phonation. The conjunctival reflex was brisk, the colour was good, and the respiration was regular. A little more of the drug abolished rigidity, though there was still brisk reflex, as was, indeed, the case all through the operation, during which narcosis was perfect. The pupils were of moderate size. The child's condition looked a perfectly normal one. After stopping the administration consciousness returned as from sleep in less than a minute. The operative anæsthesia was four minutes. There were no after-effects at all.

CASE 11. *Adenoids.*—The patient was a girl, aged 14 years. She was purely a mouth-breather, pale, and nervous. She was placed in a recumbent position with the head horizontal and a small prop in the mouth. Five cubic centimetres were sprayed on and soon another five cubic centimetres before operation. The child breathed well; after about half a minute the respiration became regular and the colour much improved; she coughed twice. The reflex was always briskly present, the pupils were of moderate size, the eyelids were tightly closed, and there was slight muscular rigidity. After about two minutes the mask was removed and the operation was performed. The patient coughed a little. She w[illegible] the end was apparently [illegible] little blood was lost and [illegible] Recovery of consciousness was rapid. The anæsthesia lasted about three-quarters of a minute or one minute—i.e., longer than with nitrous oxide. In about 10 minutes the patient, who was perspiring a good deal, had a flushed colour and a good pulse, walked upstairs. Afterwards she vomited some blood and felt drowsy till the afternoon. Ten cubic centimetres were used and probably about seven cubic centimetres were inhaled. The operator was very pleased with the result.

---

[2] Correspondenzblatt fur Schweizer Aerzte, 31. Jahrgang, No. 4.

CASE 12. *Opening and scraping a sinus, &c.; in the fore-arm.*—The patient was a thin and wiry man, about 40 years of age, of sandy colour, and very abstemious and cheerful. His chest was not examined. He was placed in a semi-recumbent position on a couch and took quietly five cubic centimetres in two doses. Operation was then attempted in about two minutes, when brisk reflex and slight rigidity were present. Then movements of the arm and leg occurred, becoming rapidly more extensive and awkward; also much phonation and excitement. Endeavours to push the anæsthetic caused much greater muscular twisting movement and writhing of the body so that the patient would have rolled off the couch if he had not been restrained. The pupils at this stage were of moderate size and the eyeballs were a little prominent. The colour was heightened. On stopping the administration the condition gradually passed off. Before the patient quite knew where he was I again began to administer ethyl chloride, but the same phenomena appeared, and yet again at the third attempt, when the patient rolled off on to the floor. The more the drug was pressed the more unmanageable the patient became, so that operation was impossible. Then I changed to chloroform, thinking that probably he would show too much excitement for me to give him gas and ether conveniently. In a minute or two he began to move and to twist awkwardly about, but then quickly passed into a condition of incoherent volubility lasting for from three to four minutes, during which the operation was finished. He very quickly recovered and was none the worse. He felt nothing of the operation at all and only remembered vaguely a sentence uttered during his going off and seemed very satisfied with the result. Thus, in this case, ethyl chloride beyond a very early analgesic stage caused excitement and irregular muscular contortive action, rendering administration impossible. There was no opisthotonos, which is said to be commonly associated with excitement. 20 cubic centimetres were used of which much was not inhaled.

CASE 13. *Adenoids.*—The patient was a tall, well-built, rather pale female, aged 18 or 19 years. She was placed in a recumbent position, with a prop in her mouth. About five cubic centimetres were sprayed on, and the patient, being very nervous at first, breathed irregularly and lightly. In about half a minute she began to cry and to struggle violently, but being restrained she took about half a dozen deep breaths and then quickly became relaxed and flushed, breathed deeply and regularly, and in a few more breaths lost the conjunctival reflex, the pupils being of moderate size. After three or four more breaths Mason's gag was inserted and operation was leisurely done during an anæsthesia which was perfect and which lasted double the length of time that was needed—i.e., from one and a half to two minutes. Recovery was quick, the patient complaining afterwards of nothing but sore throat. There was no sickness in the operating theatre. The improvement and flush of colour continued not only during the operation and recovery but also when the patient walked from the theatre eight or 10 minut[illegible] effects of any kin[illegible] half hours. The [illegible] long anæsthesia, [illegible] congestion.

CASE 14. *Adenoids.*—The patient, a girl, aged 13 years, was of the ordinary type. She had a high and narrow palate. A mouth-prop was inserted, when she breathed quietly but not deeply though regularly. She had very good colour all through. After from one minute to one and a half minutes, the pupils being contracted and the lid-reflex being present, the operation was begun. The prop was removed and Mason's gag was put in, and after about 20 seconds the patient began to move, and then during the rest of the operation she struggled violently. Analgesia lasted about one minute. The girl had no recollection of the operation. In about 10 minutes she walked back to bed. [illegible] patient nitrous oxide. [illegible] There were no after- [illegible]

[illegible] *denoids, and tonsils.*—The patient, a boy, aged 11 years, was of the ordinary type of child who has adenoid growths with a good colour and a narrow chest. He was placed in a recumbent position. The operation on the nose was performed with the head in mid-line and the chin supported. A dose of two or three cubic centimetres was given at a time. The boy breathed quietly and there was a gradual disappearance of the reflex. The drug was pushed till the pupils were rather dilated; still there were regular breathing and good colour. The inhaler was then removed. There was perfect anæsthesia for over one and a half minutes—i.e., for as long a time as was needed by the operator—then some slight movement occurred, so the inhaler was re-applied and the drug again administered till the reflex was gone and the pupils were well contracted. The gag was inserted and the adenoids and the tonsils were removed without haste during a good anæsthesia of over one minute. Perfect recovery ensued. There had been no after-effects when I left. About eight or nine cubic centimetres were used, of which a good deal remained over after inhalation.

CASE 16. *Adenoids and tonsils.*—The patient, a girl, aged 10 years and nine months, was a delicate child, with a small, long face, narrow chest, and high palate. She was placed in the recumbent posture with the head in mid-line. Mason's gag was inserted in the corner of the mouth with its blades closed. At first the child cried a little; then she breathed freely. I administered a dose of about three cubic centimetres at a time until muscular relaxation occurred and the pupils were well contracted and the conjunctiva was insensitive. There was perfect anæsthesia of about two minutes, a longer period than was needed by the operator. The patient made a very good recovery, walking upstairs to bed in 10 minutes. Ten cubic centimetres were used, of which a great deal remained over on the inhaler. A better result than this could not have been wished for.

CASE 17. *Excision of the left eye.*—The patient was a boy, aged 12 years, of the ordinary type, rather pale, and cheerful. He had just finished a good solid meal. The head was slightly raised on the pillow and about five cubic centimetres were sprayed on the inhaler. He breathed very freely and was deeply under anæsthesia in half a minute, the colour being heightened, the pupils contracted, and the colour rosy when the operation began. The inhaler was kept on for about half a minute; it was then removed, being in the operator's way. There was good anæsthesia afterwards for about three-quarters of a minute; then the patient quickly began to recover and he vomited much solid food. Before he recovered consciousness the inhaler was reapplied and by occasional inhalations anæsthesia was kept up till the end of the operation which lasted about two minutes longer. The removal of the eye was more difficult and took more time than usual. There was no evidence of shock on cutting the [illegible] effects whatsoever.

CASE 18. *Small operation inside the nose; adenoids and tonsils.*—The patient was a tall woman, aged 35 years. She was placed sitting in an ordinary chair, with her head unsupported. She manifested a good deal of excitement during induction which lasted for three and a half minutes, but she was quiet during the nasal operation and removal of one tonsil; then there were much muscular excitement and spasm ending in opisthotonos, so that the patient rested on her heels and on her supported head. When she recovered she was placed in a semi-recumbent position on a couch, the blades of Mason's gag were inserted in her mouth, and after a very long (from four to five minutes) administration of ethyl chloride the adenoids and tonsil were removed.

The patient looked rather pale afterwards. This was an unsatisfactory case

CASE 19. *Adenoids.*—The patient was a very anæmic girl, aged 19 years, with red hair. She was very excited. She was placed sitting in a chair with her head unsupported. She did not breathe well. I freely sprayed on ethyl chloride, but the conjunctival reflex was only dulled after five and a half minutes, when the operation was begun. The patient came round so quickly that it could not be completed, so she was placed in a semi-recumbent position and after a few more minutes' administration till the reflex was almost gone the operation was finished. She quickly recovered and went home in half an hour. No after-effects were noted. An unsatisfactory case.

CASE 20. *Slight adenoids.*—The patient was a woman, aged 23 years. She was placed in a semi-recumbent position. After an administration of two and a half minutes the conjunctival reflex was much dulled. There was fair operative anæsthesia of three-quarters of a minute. In a few minutes the patient walked away. She felt rather sick after the operation, probably because she had swallowed some blood.

In the last three cases the conditions were altogether unfavourable, as no operating chair or table was at hand, while the patients were very nervous and excited.

CASE 21. *Adenoids.*—The patient, a sturdy girl, aged five years, was laid flat on the table. She cried at first but breathed well and was fully under in three-quarters of a minute. The eyeballs were turned inwards; the pupils were of moderate size; the sclerotic was insensitive. The patient was of very good colour and her muscles were lax. Mason's gag was introduced and the head was lowered over the end of the table; very good anæsthesia of about three-quarters of a minute was obtained. She made an excellent recovery.

CASE 22. *Adenoids.*—The patient was a girl, aged 19 years, dark, and pale. She exhibited very slight excitement during the induction which lasted for from one minute to one and a half minutes—i.e., till the conjunctival reflex was abolished and the pupils were well contracted. Mason's gag was inserted. The operative anæsthesia was from three-quarters of a minute to one minute. There were no special after-effects.

CASE 23. *Adenoids.*—The patient was a girl, aged 20 years, of ordinary physique. She was very nervous and cried rather at first; then she breathed regularly and in one and a half minutes was well under anæsthesia. The eyeballs were turned in. There was no reflex and very slight muscular rigidity. Mason's gag was inserted and a very good anæsthesia, lasting from one and a half to two minutes, was gained. The patient made an excellent recovery. The case showed a far better result than would have been obtained from nitrous oxide which was the alternative anæsthetic.

CASE 24. *Iridectomy.*—The patient was a slightly-built boy, aged 11 years. His other eye was of glass. He cried a little at first, but was under anæsthesia in one and a half minutes. After three-quarters of a minute's anæsthesia the patient began to move, so the inhaler was reapplied, as the operation proved rather complicated, till the patient was quiet. It was again reapplied from time to time for the next few minutes to maintain anæsthesia. The patient made an excellent recovery and felt nothing.

CASE 25. *Tonsils and adenoids.*—The patient was a pale, delicate, cheerful girl, aged 12 years. The heart was slightly enlarged and was excitable. The tonsils were very large. She was placed in a recumbent posture and Breuer's inhaler was applied. Two or three cubic centimetres were sprayed on at first and then as breathing became regular five cubic centimetres more and at the end again two or three cubic centimetres. Gradual and quiet induction of deep anæsthesia ensued, the pupils beginning to dilate and the conjunctiva being insensitive. The patient was of excellent colour; the breathing was regular and rather snoring and the muscles were lax. The mask was removed and Mason's gag was inserted. The tonsils and then the adenoids were removed deliberately, and at the end of the operation there was yet about half a minute's anæsthesia to spare. The patient then quickly vomited some blood and some curdled milk which had been given by mistake an hour previously. She walked back to bed in a few minutes and was again sick, bringing up more blood and milk. Ten cubic centimetres were used altogether, much of which remained over on the mask. Had nitrous oxide, the alternative drug, been given in this case and in the usual way, the congestion of the parts, and especially of the tonsils, would have embarrassed respiration before full anæsthesia had appeared. There would besides have been cyanosis, spasm, and inconvenient jactitation, and probably an anæsthesia of half a minute at most. Had nitrous oxide mixed with oxygen been administered, though those awkward symptoms would have been absent, the resulting anæsthesia would have been at the utmost only half as long as that gained by the use of ethyl chloride.

CASE 26. *Scraping carious bone of the arm.*—The patient was a plump, anæmic girl, aged 19 years. Examination of the chest revealed nothing. She was placed in a recumbent posture. Two or three cubic centimetres were sprayed on at first and later five cubic centimetres. There was no excitement; the patient held her breath a little at first, but was unconscious in half a minute. She was then wheeled into the theatre and placed on the operating table. By this time deep anæsthesia as of chloroform had been induced. The pupils were contracted and the conjunctiva was insensitive. The colour was good, the breathing was regular, and the limbs were lax. After three minutes' good operative anæsthesia the inhaler was removed before the insertion of the last two sutures. Recovery took place in about a minute, ending with a very little retching. As the dressings were being applied the patient began to cry, but she felt no pain. On her return to the ward she vomited once slightly and then said that she felt well, but later in the afternoon she had some frontal headache. These after-effects were infinitely less than after gas and ether which she had had recently. Three and a half hours after the operation the patient had a good tea. About 10 cubic centimetres were used, with a remainder. Thus a good deep anæsthesia corresponding in depth to that of ether or chloroform was obtained in this case and I could easily have much prolonged it.

In all of the adenoid cases nitrous oxide, failing ethyl chloride, would have been administered, and the operator in most cases found much advantage in ethyl chloride over nitrous oxide as giving a much longer anæsthesia, usually lasting from three-quarters of a minute to two minutes, and causing no congestion while apparently having a distinctly stimulative action. In the recumbent position at any rate I think that the insertion of a mouth prop before beginning the administration rather hinders free breathing and upsets the patient. It is, I find, preferable to place the closed blades of a Mason's gag in the corner of the mouth and even better to insert the instrument when full anæsthesia has been induced. The drug should be given until the pupils are contracted or just beginning to dilate, and till the conjunctiva is insensitive and full muscular relaxation has occurred. Then the mouth can be easily opened and the operation proceeded with. Ethyl chloride has obviously great advantages over gas in these short adenoid operations where an extra minute or half a minute of anæsthesia makes all the difference to absolute success. On the average I use between five and 10 cubic centimetres in these cases, much usually remaining over. It would seem that in many short ear and nose operations ethyl chloride might also be used with great advantage. In ear, nose, and throat work there is apparently no objection to administration in the sitting-up position, a great gain to the operator in that the usual relative position of surgeon and patient is maintained. In the operation for excision of the eye I rather feared that there might be evidence of shock on the section of the optic nerve, and was agreeably surprised to observe none. I hope to try ethyl chloride in operations for strabismus, and as I have given gas and oxygen successfully in several of these procedures I think that it will answer even better. In dental work nitrous oxide suffices for very short cases when given in the ordinary way. For slightly longer cases ethyl chloride would be very advantageous, but for the longest cases of all—those, say, lasting for from three minutes to 10 minutes—nitrous oxide given by the Coleman-Paterson method answers every purpose since it can be continuously used during operation. I frequently thus administer nitrous oxide in hospital and private dental operations for periods of time between two and 10 minutes, and am perfectly satisfied with my results in the great majority of cases. Seitz of Constance, a well-known dental surgeon and writer on dental subjects, in a recent work on dental narcosis strongly recommends ethyl chloride for dental operations instead of nitrous oxide or ether.

If the patient be very strong and very excitable, and especially if he be an alcoholic, and it be attempted to administer ethyl chloride it is advisable to have both ether and chloroform to hand as instanced in the case of the patient in Case 12 who showed great muscular and mental excitement. According to Lotheissen, Wiesner, and others excitement is chiefly shown by alcoholics, but the patient I have just referred to was an abstemious man.

After-effects have in all my cases been slight or absent altogether.

A rather better inhaler in one or two respects than Breuer's original one, though the same in principle, can now be obtained from Messrs. Allen and Hanburys or from Messrs. Greeff. It is made in three sizes. In neither of them is the air-way quite free enough for a large-chested patient. Probably an Ormsby's ether inhaler of the pattern made with an air-inlet would serve very well for short inhalations at any rate. I think that, contrary to the custom of some administrators who "crowd" on the anæsthetic, dosage should be by gradually increasing additions of small quantities of the drug, say two or three cubic centimetres at a time, until anæsthesia is attained and then about the same amount given per minute will generally be enough to maintain narcosis. There is decidedly a disadvantage in pouring out at the first a full dose, pressing the inhaler very firmly on the face, and keeping it on in spite of crying and struggling till the patient is under. By this method over-dosage may occur and the patient will not forget the terror and feeling of suffocation during the induction of narcosis.

The case of death after operation under the influence of ethyl chloride in no way shakes my present opinion of its value as a narcotic and I have since then taken every opportunity of trying it for the shorter surgical operations. Finally, so far as I can now judge, ethyl chloride might advantageously be used instead of nitrous oxide mixed with oxygen or nitrous oxide alone for many of the shorter operations, and more especially in the case of less vigorous patients.

irmingham.

HEADACHE.[1]

BY A. H. COPEMAN, M.A., M.D. DUB.,
M.R.C.S. ENG.

THE success of the general practitioner depends very largely on the ability and resource which he exhibits when confronted with the commoner, or so-called minor, ailments which afflict mankind. Prominent in this class stands headache—a condition deserving our very best attention if only on account of the immense amount of suffering which it occasions and of the increasing numbers of its victims in these days of luxurious living, rapid locomotion, and higher education. Headache may have its seat in the scalp, in the bone of the skull or its pericranium, or in the brain itself and its membrane. As instances of the first kind we have neuralgia of the fifth and other nerves. Specific disease or mechanical injury may set up painful inflammation of the bone, while the vast majority of headaches are intracranial.

Intracranial headaches may be briefly classified as follows: (1) headache the result of gross lesions of the brain or of the vessels or membranes of the brain; (2) headache occurring at the onset of the acute fevers, especially that of typhoid fever; (3) congestive headache; (4) anæmic headache; (5) nervous headache; (6) toxæmic headache; (7) sympathetic or reflex headache; and (8) migraine or sick headache.

Headache the result of brain lesions and acute fevers.—This is usually associated with other symptoms pointing to the gravity of its origin, and in such cases it is obviously the duty of the physician to fix his attention less on the headache itself than on the disease of which it is a symptom. I do not propose to refer further to headaches coming under this category beyond remarking that the presence or absence of fever, as proved by the clinical thermometer, should be of most important service to us in eliminating fevers and intracranial inflammations. The age of the patient and the condition of his arteries should also be [illegible] Again, in the case of tumours [illegible] pain is apt to be terrible in its persistency and nausea and vomiting are nearly constant concomitant symptoms; the ophthalmoscope would almost certainly afford us valuable information and sooner or later paralyses of the cranial and other nerves might become apparent.

Congestive headache.—This may be either active or passive. Both conditions may be produced by valvular disease of the heart: active congestion being the result of hypertrophy of the left ventricle, as in the headache of chronic interstitial nephritis; passive congestion occurring in lesions of the mitral orifice and conditions leading to dilatation of the right heart. Plethoric persons of middle age with too great a fondness for the table and none for open-air exercise are also very liable to this form of headache. Irregular menstruation and emotional disturbances may also be factors in the case, while cases of interest, occasionally met with in private practice, are those arising from the use of tight collars and the abuse of corsets. The pain is generally of a dull description, often affecting the whole of the head and accompanied by flushings of the face, ringing in the ears, and giddiness and [illegible] symptoms on stooping. When [illegible] condition of the heart aconite i[illegible] repeated will be of great service by slowing and calming its action. In passive congestion, on the other hand, digitalis and other heart tonics are called for and opium in small doses is often of benefit. In both cases sal volatile is of use and often results in great immediate relief. Many such cases automatically relieve themselves by the onset of epistaxis; cold affusions to the head, saline purges, and hot mustard footbaths are valuable accessories. Where there is much congestion of the portal system an emetic and free purgation will be of considerable service as a preliminary to further treatment. Afterwards the patient must be enjoined to take gentle exercise in the open air and to deny himself some of the pleasures of the table, having special regard, more particularly in the cases of active congestion, to the quantity of alcoholic liquor consumed.

Headache of cerebral anæmia.—This is generally vertical and is often of a very acute and persistent type, being, indeed, the symptom which usually drives the patient to the medical man in the more extreme grades of general anæmia; it is a very common form amongst all classes and in people of all ages. In chlorotic young girls the cerebral anæmia is only one of the manifestations of the general poverty of the blood; in old age, on the contrary, the blood itself may be in perfect order but the cerebral vessels obstruct the passage of the blood either by loss of elasticity or actual narrowing of their lumen. At all ages a weak action of the heart, whether functional or organic, may be the means of starving the brain of its needful supply of oxygenated blood. Few drugs are of any immediate benefit in this condition when it is the result of general anæmia or chlorosis, but the improvement so rapidly produced by the exhibition of iron is, of course, among the marvels of therapeutics. A glass of wine, preferably champagne as being the more rapidly diffusible, or, in contra-distinction to the congestive headache, even the mere taking up of the recumbent position will do more good at the moment than any of the so-called specifics, and I have no doubt but that much harm is done by the persistent use of these "pain-killers" in patients whose blood is already in a sadly impoverished condition. One of the symptoms in cases of poisoning by various coal-tar derivatives is the appearance of hæmato-porphyrin in the urine, showing that the red corpuscles are being disintegrated by the action of the poison. In old age alcoholic and other diffusible stimulants will give the best results, and of course in the case of there being a weak and irregular action of the heart cardiac tonics will be indicated.

Nervous headache.—This is the headache of general debility and neurasthenia. It may occur in any part of the cranium and is often fixed in one small spot, as in the Clavus Hystericus of the neurotic girl. This type of headache bears a very close relationship to the anæmic form. Migraine, which generally occurs in patients of the nervous diathesis, should perhaps be included under this heading, but will be discussed later by itself. Over-lactation and worry in weakly women, excessive study, over-application to business, and the excesses of youth, must all share the responsibility for the increasing numbers of the patients of this class. Especial care is necessary in dealing with them to avoid, if possible, [illegible] analgesics lest a habit be [illegible]r degrading in its results [illegible]omania. Excellent results will be obtained from the use of sal volatile, the bromides, and camphor, with perfect rest and quiet in a darkened room; and a most important need is to brace up the exhausted nervous system in the intervals between the attacks by the intelligent use of the dilute mineral acids, the various preparations of iron, zinc, and arsenic. Alcoholic stimulants are best avoided and where iron and arsenic disagree cod-liver oil is of good service in improving the general nutrition. Phosphorus, especially in the form of the hypophosphites, is also to be highly recommended.

---

[1] Thesis for the degree of M.D., Trinity College, Dublin.

Toxæmic headaches.—These form the group perhaps most frequently met with of all and are the result of the introduction into the blood of poisons of many and diverse descriptions. The headache of fevers might accordingly be classified under this heading. Dyspeptic and bilious headaches are in reality toxic, the products of faulty digestion and of the imperfect action of the liver finding their way into the general circulation. Other forms of headache belonging to this class are those of acute alcoholism, uræmia, gout, rheumatism, malaria, and lead-poisoning, and also no doubt those arising from confinement in close, stuffy, and ill-ventilated rooms and from the inhalation of sewer gas. Toxæmic headache is more frequently frontal and in the dyspeptic and bilious forms finds prompt relief from the exhibition of an emetic followed by a brisk mercurial purge, with, if possible, complete rest to the stomach in the shape of actual starvation for from 12 to 24 hours. Quantities of pure water may be drunk with advantage and the irritated stomach may be soothed with a few doses of the liquor bismuthi and the dilute hydrocyanic acid in an effervescing draught. In the malarial headache which is still exceedingly common in the fen districts of England opium has long been considered a specific, but five grains of quinine dissolved in half a drachm of the dilute hydrobromic acid is every bit as serviceable and is not open to the same objections as is the continued use of opium. In the gouty, rheumatic, and other toxæmias the appropriate remedies for the primary condition will afford the means of effecting a cure, but in that particular form of rheumatic pain affecting the muscles and aponeurosis of the scalp perhaps more benefit may be expected from the external application of belladonna, chloroform, and other soothing liniments.

Sympathetic or reflex headache.—This may be the result of eye-strain from over-use, as in prolonged microscopical work, of mere general debility, or of errors of refraction or some muscular insufficiency, as of the external rectus muscle, and this is a very frequent cause of persistent headache and one which is very likely to be overlooked in the hurry of general practice. Dental caries, diseases of the throat and nasal passages (as in the headache of enlarged tonsils), and ovarian and sexual derangements are well-known culprits. Attention to the organ whence the irritation springs is the only means of giving relief to the sufferer.

Migraine or sick headache.—This, the most intractable of all forms of functional headache, has been the subject of endless dispute amongst pathologists and is now generally thought to be due either to a so-called nerve-storm of the nature of epilepsy or to some other ill-defined disturbance in the cortex of the brain. Others trace it to profound alterations taking place in the circulation of the brain, and it is generally agreed that it is not due to gastro-hepatic derangement but that the cerebral disturbance constitutes the primary lesion. The undoubted influence of neuropathic heredity in this affection is often brought forward as a proof of its central origin, but in practice we find the bilious and gouty habits equally hereditary, and many sufferers from typical migraine find more relief from the old-fashioned blue pill and emetic than from the more modern methods dictated by the pathologist. I have had several patients who have been able to avert the threatened seizure by the prompt exhibition of five grains of calomel. I am myself strongly inclined to place migraine in the toxæmic group and to refer the symptoms to profound poisoning of the substance of the brain by a blood loaded with the toxic products of incomplete and faulty digestion. But little can be done for the unfortunate sufferer after the incidence of the attack. I am in the habit of prescribing a powder consisting of five grains of phenacetin with two grains of caffeine, but from 12 to 24 hours' rest and a night in bed will be necessary before complete relief will be secured.

Cowes, Isle of Wight.

THE PROGNOSIS AND TREATMENT OF CASES OF ASCITES OCCURRING IN THE COURSE OF ALCOHOLIC CIRRHOSIS OF THE LIVER,

WITH SPECIAL REFERENCE TO THE TREATMENT BY OPERATION.[1]

BY H. CAMPBELL THOMSON, M.D., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN AND PATHOLOGIST TO THE MIDDLESEX HOSPITAL.

THERE is at the present time a considerable want of unanimity regarding the prognosis of cirrhosis of the liver after the appearance of ascites. Formerly all such cases seem to have been looked upon as hopeless, but at the present day, while their extreme gravity is fully recognised, a somewhat more hopeful view is taken of them, based upon the fact that a number of cases have been recorded in which the ascites has temporarily, or even permanently, disappeared after tapping. Dr. W. B. Cheadle, in his recent Lumleian Lectures, has shown that much of the confusion regarding cirrhosis of the liver has arisen from a failure to differentiate between the several types and stages. It is, as Dr. Cheadle clearly shows, of great importance to distinguish the different stages and varieties if any real advance is to be made, and it seems to me that this importance has become still more imperative in face of the fact that an operation for "cirrhosis of the liver" has recently been introduced—an operation which will probably meet with but little success unless the cases are carefully selected.

The subject is a wide one and necessarily somewhat difficult to summarise, but I have endeavoured to collect information from the works of others and from my own experience which will, I hope, among other things, show the following points:—1. That ascites arising during the course of a case of alcoholic cirrhosis of the liver may be due either (*a*) directly to the cirrhosis or (*b*) may depend upon some condition co-existing with the cirrhosis. 2. That ascites when directly dependent upon the cirrhosis is almost always a fatal symptom, while, on the other hand, ascites associated with cirrhosis, but not directly dependent upon it, may often be temporarily relieved and not unfrequently cured. 3. That under these circumstances laparotomy performed on cases of cirrhosis of the liver with ascites is only likely to be successful in those cases in which the ascites is an associated condition of the cirrhosis and not directly dependent upon it, and that if this is so it would seem misleading to look upon the operation as being one for the cure of cirrhosis of the liver; it should rather be looked upon as one for the relief of cases of ascites, some of which, although occurring in the course of cirrhosis of the liver, may still be amenable to treatment.

In the first place it will, I suppose, be granted by everyone that the condition of cirrhosis itself cannot be cured—i.e., the connective tissue when once formed cannot be got rid of by drugs or any other means at our disposal. That an advanced condition of cirrhosis may remain latent is true and that it may become arrested is possible, but it cannot be cured. The question then arises as to how far symptoms may be relieved, and especially the ascites, which is frequently the first thing which causes the patient to seek advice. The recoveries which have taken place after the onset of ascites are attributed to a development of the collateral circulation, whereby the blood in the portal veins finds its way directly into the systemic circulation without passing through the liver, and on this supposition the usual custom in cases of ascites associated with alcoholic cirrhosis is to give a guarded prognosis, always bearing in mind that in a certain small percentage of patients the ascites disappears after tapping.

That patients recover from ascites, which clinically appears to be due to cirrhosis of the liver, is perfectly true, and it is equally true that recoveries take place from ascites associated with cirrhosis, but it is probable that it is only very rarely indeed that recoveries take place when the ascites is directly due to the cirrhosis. This certainly seems to have been the view held by authorities a few years ago. In

[1] A paper read before the Royal Medical and Chirurgical Society on June 11th, 1901.

Reynolds's "System of Medicine" the following passage occurs: "It is probable that in patients in whom very free collateral circulation is established the progress may be slower, as cases are on record in which ascites has disappeared when the various venous anastomoses have been largely formed. It is possible that in such cases of free restoration of circulation by means of collateral channels, if the uninjured portion of the liver be sufficient for the purposes of life and the atrophy arrested, that existence may be maintained; but there does not appear to be good evidence of such cases and results having occurred." Dr. J. S Bristowe,[2] in speaking of cases of cured ascites, clearly recognises the ascites which may be associated with cirrhosis from that which is directly due to it, for he says: "We have reason, therefore, to believe that the ascites which appears in the course of [illegible] occasionally [illegible] remediable [illegible] or permanent [illegible] though the hepatic disease be still progressing towards its inevitable fatal termination." More recently a valuable contribution to the subject has been made by Dr. W. Hale White[3] who found that many cases of ascites which during life were thought to be due to hepatic cirrhosis were proved after death to depend upon something quite different, and in others which were tapped frequently there was some other cause present besides the cirrhosis which would account for the ascites, the most frequent being chronic peritonitis and perihepatitis Dr. Hale White concluded that when ascites depends upon cirrhosis of the liver the patient rarely lives long enough to survive more than one tapping and he published 34 cases [illegible] 10 suffered from cirrhosis [illegible] was necessary; the averag[illegible] was first noticed to be enlarging was only eight weeks. 14 were undoubted cases of cirrhosis in which paracentesis was performed and not one of them survived the first tapping long enough to render a second tapping necessary and in not one was there any evidence that the tapping was beneficial. 10 cases were regarded during life as having cirrhosis and were tapped more than once; of these the diagnosis proved to be wrong in four cases, while the remaining six cases had chronic peritonitis associated with the cirrhosis Dr. White's teaching upon this subject is, I think, so generally accepted that it scarcely needs any corroboration; but as I have made a number of post-mortem examinations upon cases of cirrhosis during the past two and a half years I have collected them and also looked up some others from the post-mortem records of the Middlesex Hospital, making altogether 18 cases, and on referring to their clinical histories the seriousness of the disease is well seen and their results in every way support Dr. White's conclusions. 12 of the 18 died before tapping was necessary or soon after it had been performed once. Six survived more than one tapping, and in these, with the possible exception of one, there was adequate cause for the ascites in addition to the cirrhosis. The cases which survived only one tapping ran a very similar course to those recorded by Dr. White, dying within a few weeks of the onset of the ascites.

When the ascites is associated with the cirrhosis the prognosis, as far as the ascites is concerned, depends upon the stage of the cirrhosis at which it arises. It would seem that the associated ascites in cases of cirrhosis is also usually a late symptom, which accounts for the great fatality of this condition, which, although considerably less than the cases dependent directly upon the cirrhosis, is still great, only a case here and there doing well for any length of time. The results of post-mortem examinations show that the cases of ascites which during life appear to be due to cirrhosis of the liver may be divided into three groups: (1) those in which the diagnosis of cirrhosis is erroneous, the ascites being found after death to be due to some entirely different cause; (2) those in which ascites is associated with cirrhosis, but actually due to some other cause; and (3) those in which the ascites is directly dependent upon the cirrhosis.

1. The first division of this group need not now be considered except for the purpose of emphasising the necessity of basing the evidence of cures upon ultimate post-mortem examinations. The liabilities of making errors in the diagnosis of the causes of ascites are very great, and as an example a case recorded by Dr. Ewart may be mentioned in which the patient was tapped 52 times and also had laparotomy performed on the supposition, which was proved afterwards to be erroneous, that the ascites was due to cirrhosis.

2. The commonest cause of ascites associated but not directly dependent upon cirrhosis of the liver is undoubtedly chronic peritonitis and perihepatitis. Dr. Hale White's cases show this and my own post-mortem experiences fully support the frequent association of this condition. Dr. Bristowe, in discussing the causes of ascites,[4] alludes to the part which changes in the capsule of the liver play as follows: "This formation, which is probably of inflammatory origin, is sometimes associated with cirrhosis or other morbid states of the liver, but is sometimes present when the liver seems otherwise perfectly healthy, and where it is the sole visible pathological phenomenon associated with ascites." It may, then, I think, be fairly considered that the ascites associated with latent cirrhosis is very frequently due to these conditions.

3. The third group comprises those cases in which the ascites directly depends upon the cirrhosis, and the prognosis here appears to be very bad, the majority of cases dying within a few weeks after ascites has first been noticed. The average duration of life after the onset of ascites in Dr. White's cases was only two months, and the collection of cases which I have made shows an equally grave prognosis. Indeed, many cases of cirrhosis die before tapping becomes necessary, and out of 46 cases in which cirrhosis was discovered after death in 20 only was there more or less accumulation of ascitic fluid (Bristowe), facts which all point to ascites being a late symptom. If, then, it is recognised that ascites is frequently produced by chronic peritonitis and perihepatitis, it is no proof of the curability of ascites due to cirrhosis to cite cases in which these conditions are present. In order to prove the curability of ascites due directly to cirrhosis, post-mortem evidence must be obtained of uncomplicated cases of cirrhosis which have been tapped one or more times at some date previously and afterwards lived in good health. Such cases no doubt do occasionally occur, but I think they must be extremely rare and considered as exceptions which in no way alter the general aspect of the question. Personally, during the time that I have been pathologist at the Middlesex Hospital I have never met with such a case. Dr. W. B. Cheadle has recorded in his recent lectures five cases which he has met with as great examples of improvement in atrophic cirrhosis. One of these was eventually lost sight of and therefore cannot be regarded as a proved case. Of the remaining four, upon which post-mortem examinations were ultimately made, the following are brief extracts of the conditions present.

CASE 1.—A woman, aged 53 years, was admitted into the hospital suffering from ascites and hæmatemesis; she was tapped twice and left the hospital in two months free from ascites. Nine months later she was readmitted with ascites and she was again tapped. There was no return of ascites but the patient had a severe attack of pleuro-pneumonia, from which she recovered, but she died a month later from acute bronchitis. At the post-mortem examination there was found a typically hobnailed, cirrhotic liver, weighing 38 ounces, with thickened capsule, but no general perihepatitis or peritonitis; nor were there any thickening of, or adhesions to, neighbouring structures.

CASE 2.—The patient, a man, aged 43 years, died one and a half years after first coming under treatment for ascites. At the post-mortem examination the cirrhotic liver was found to be covered with thick false membrane.

CASE 3.—The patient, a female, survived the first treatment of ascites one and a half years. She was tapped four times. At the post-mortem examination abundant adhesions were found between the liver and the neighbouring organs.

CASE 4.—A man, aged 35 years, was tapped 11 times and also had laparotomy performed. The post-mortem examination showed atrophic cirrhosis. Perihepatitis was also present.

On examining these four cases it will be seen that in three of them at least there were signs of perihepatitis and peritonitis, which therefore may have caused the ascites. In Case 2 the liver was covered with a thick false membrane; in Case 3 there were abundant adhesions between the liver and neighbouring organs; and in Case 4 definite perihepatitis is recorded. In Case 1, on the other hand, there does not appear to have been any cause for the ascites except the cirrhosis, and it appears to be one of the exceptional examples of a temporary recovery.

[3] The Causes and Prognosis of Ascites, Guy's Hospital Reports, 1892.

[4] Reynolds's System of Medicine.

Dr. H. Hawkins[5] concludes that after ascites has set in "the conditions necessary for the restoration of health must be very rarely attained." The clinical course of cirrhosis of the liver may then, I think, be summed up as follows. Cases may exist for years without any ascites, or indeed without any definite symptoms, but during this period ascites is liable to arise from some associated condition, the most common being chronic peritonitis and perihepatitis. Ascites arising from this cause may be frequently relieved and occasionally it eventually entirely disappears, and the patient then returns to his former state of latent cirrhosis without any ascites. As time goes on the cirrhosis progresses until frequently it itself gives rise to ascites, for which tapping is of no avail, and the patient succumbs a few weeks after its onset. Of course, there need not be, and frequently is not, any long interval between the first and last tapping, as the associated ascites often merges imperceptibly into that directly dependent upon the cirrhosis. Examples of these are to be found in cases which are tapped repeatedly and survive for a few months. In fact, all stages may be frequently seen except that of an uncomplicated cirrhosis which has survived several tappings and recovered, and there is but little post-mortem evidence of the occurrence of this condition. This view would also seem to be in harmony with clinical experience regarding the difference in the prognosis of ascites in large and small livers. Dr. Cheadle in discussing prognosis says: "To put it broadly, and speaking clinically, the cases which do well are those in which the liver, apparently large, exposes a flat, hard surface to the abdominal front, extending far below the edge of the ribs and sometimes down to the umbilicus." Now it is precisely in these large livers, which are almost certainly in many cases the early stages of the smaller ones, and therefore presumably in an early stage of the disease, that the ascites is more likely in many cases to be due to an associated condition, and not in that early stage so likely to be directly dependent upon the cirrhosis, and, this being so, cases of ascites with large livers would be likely to do better than those with small livers, which, as already stated, Dr. Cheadle has shown to be the case.

TABLE OF CASES OPERATED UPON FOR ASCITES DUE TO CIRRHOSIS OF THE LIVER.

Case	Operator.	Age.	Sex.	Previous history and conditions found at operation.	Result.	Remarks.
1	Drummond and Morison.	42	F.	The liver was enlarged, pale, and smooth, but not harder than normal.	Recovery from operation; recurrence of ascites.	The patient required frequent tappings (69 times between date of operation and death). She died 19 months after the operation. No necropsy.
2	Drummond and Morison.	39	F.	The patient was tapped frequently before operation; the liver was found to be "typically cirrhotic."	Recovered; no return of ascites.	The patient was perfectly well at the end of two years. She finally died after an operation for ventral hernia. At the necropsy there were found adhesions with vessels, some of them of large size, passing between the omentum and the viscera to the parietes; the liver was atrophic and degenerated; the spleen was about four times its natural size.
3	Morison.	42	M.	The illness was of about eight weeks' duration. The liver was cirrhotic, but not so contracted as was expected; the spleen was enlarged.	Recovered; no return of ascites.	The patient was known to be quite well two years after.
4	"	54	M.	There were cirrhosis of liver, enlargement of spleen, and ovarian cyst.	Died.	At the necropsy partial examination showed the patient to have contracted kidneys.
5	Schelky.	—	—	—	"	The patient died from delirium tremens.
6	Lens.	61	M.	The liver was atrophic.	Recovered; ascites recurred.	The patient was tapped five times before death, which occurred six months after the operation.
7	Talma.	9	M.	The liver was enlarged and its surface was granular; there were splenic enlargement and parenchymatous nephritis.	Recovered; no recurrence of ascites.	The patient was perfectly well 26 months after operation.
8	Neuman.	45	M.	There was enlargement of the spleen.	Recovered; no recurrence of ascites six months after the operation.	—
9	Weir.	39	M.	The liver capsule was thickened and the spleen was bound down by adhesions.	Died on the fifth day after the operation.	Purulent peritonitis.
10	Rolleston and Turner.	52	M.	There was ascites of two months' duration; the patient had been tapped twice before operation; the liver was markedly cirrhosed.	Recovered; recurrence of ascites requiring frequent tapping.	When heard of about four months afterwards the patient was ill in bed with distended abdomen and œdema of the legs.
11	Rolleston and Turner.	45	M.	There were œdema of the feet and ascites of about a month's duration, preceded by hæmatemesis; the liver was markedly hobnailed but was free from adhesions; the peritoneum was much injected.	Recovered; remained much improved; four months after there was, however, a trace of ascites and some œdema of the feet.	—
12	Bossowski.	9	F.	The liver was cirrhotic.	Recovered; recurrence of ascites.	The recurrence of the ascites appeared to take place less rapidly after the operation.
13	Frazier.	45	M.	The liver was cirrhotic; the omentum was short and thickened.	Recovered; recurrence of ascites for a time.	The patient required tapping twice after the operation; after that there was no return of ascites at the end of three months.
14	Van de Meule.	—	—	—	Died.	—

TREATMENT.

The treatment of the later stages of cirrhosis of the liver consists chiefly in attempting to relieve the ascites, which can in most cases only effectually be done by tapping. Formerly it was always considered wise to put off tapping as long as possible, now it is generally advised to tap early. This diversity of opinion has no doubt arisen from a confusion as to the actual causes of the ascites, some cases being benefited by this treatment and others not. Without, however, going further into the question as to whether tapping should be performed early or late, it may at once be stated that there is no good evidence to show that tapping is of any benefit in those cases where the ascites is directly dependent upon the cirrhosis. Dr. White found that in 14 cases the length of life after tapping was usually only a few days (the shortest was two days, the longest 40), and, as

---

Cirrhosis, Allbutt's System of Medicine.

already stated, patients in this group of cases seldom live long enough to require tapping more than once or twice.

Recently a more radical operation has been introduced with a view of curing cases of cirrhosis with ascites. First introduced into this country by Morison and Rutherford, the operation consists briefly in opening the abdomen and promoting adhesions between the peritoneum, the omentum, and the parietes, the idea being to establish a free collateral circulation which shall relieve the portal system and so prevent the recurrence of ascites. This method of treatment has met with a certain amount of success and I append a table of those cases which I have been able to find particulars of. I have adopted the following table chiefly from a paper by Frazier,[6] but have made various additions to the details where I have been able to find them.

It is very difficult to draw any definite conclusions from this table, since the cases operated upon are so various and often likewise complicated. It is, indeed, rather a table of operation for ascites from various causes than one in which the ascites can be said to be due to cirrhosis. For instance, in Case 4 in the table there was an ovarian cyst and in Case 7 there was parenchymatous nephritis. If, however, we consider for the moment that these cases represent the general run of clinical cases which are diagnosed as cirrhosis with ascites it will be interesting to see how the results compare with those of tapping.

In this table we have, out of 14 cases, four which may be regarded as cured of the ascites, or, at any rate, very greatly benefited; they are Morison's cases (Case 2 and Case 3), in both of which the patients were well two years after; Talma's case (Case 7), where the patient was well 26 months after; and Neuman's case (Case 8), in which there was no recurrence of ascites six months after operation; while two others (Case 11, Rolleston and Turner, and Case 13, Frazier) appear to have been considerably improved, but cannot be regarded as cured, since in one (Rolleston and Turner) there were definite traces of ascites and œdema of the feet four months after, and in Frazier's case the patient required tapping twice after the operation, and the record of freedom from ascites only extends for three months.[7] In making a comparison with tapping it must be remembered that many cases which are operated upon are those which have already survived several tappings and therefore, as has been already shown in the first part of this paper, these are to a large extent removed from the more serious group, which die after the first tapping, and, further, it must be remembered that successful cases are more likely to be recorded than unsuccessful ones.

If now we take the records of a similar set of clinical cases diagnosed as cirrhosis and ascites like the above, without any attempt to further classify them into the groups I have previously mentioned, we shall similarly find a considerable number of cases greatly relieved and a few that have quite recovered. Dr. Cheadle, for instance, quotes 11 cases in which recovery was either temporary or prolonged, exclusive of those in which there was mere relief of symptoms sufficient to admit of discharge from hospital, or private cases which were not traced afterwards, which is a very large percentage and one which I venture to think will compare very favourably with the statistics of cases operated upon.

Those who consider the operation as one for cirrhosis of the liver look upon the ascites as being due to mechanical causes and capable of being relieved by the establishment of a free collateral circulation. There are, however, good reasons for believing that the occurrence of ascites is not capable of such a simple explanation, and it is thought by many that it may be due to a toxæmia which accompanies the later stages of the disease. That there is congestion of the portal system in cirrhosis there can be no doubt, as evidenced by hæmorrhages and frequent enlargement of veins, but that it will explain many of the later symptoms, including the ascites, is not so certain. Moreover, there does not seem to be any evidence at present that the operation has been successful in an uncomplicated case of cirrhosis with ascites. Morison advises operation after one or two tappings; in his conclusions regarding the operation he says: "It is no longer advisable to treat the cirrhosis by repeated tappings if the patient is otherwise sound and in fair general condition. After one or two tappings have failed operation offers the best chance of prolonged and useful life." Frazier considers the chief indication for the operation to be the presence of ascites due to obstruction of the veins of the portal system, when the obstruction itself is due to cirrhosis of the liver, but qualifies this later by stating that the cases which should be operated upon are those to which paracentesis has failed to give relief. Another view, suggested by Rolleston, is that the operation gives relief by affording increased nutrition to the liver and promoting hyperplasia of the cells, and on this ground he thinks that operative interference would probably succeed better in the pre-ascitic stages than in the later ones, but considering how long the disease may remain latent and the uncertainties of its course this suggestion is scarcely practicable. There is, however, I think, one other possible explanation simpler than both of the above, and that is that the beneficial effects which follow the operation are simply due to the formation of adhesions between the two layers of the peritoneum and so leading to obliteration of its cavity. This would in itself be sufficient to account for the non-return of ascites, without any necessity for explaining it either by the development of a collateral circulation or by increased nutrition of the liver cells, both of which would require very strong evidence of their existence before they can be accepted as facts.

Obliteration of the peritoneal cavity, partial or complete, is not unfrequently seen in the course of tuberculous peritonitis and the same process of obliteration, of course, often occurs in connexion with the pleura and pericardium. An interesting case in which obliteration of the peritoneal cavity apparently occurred after tapping has been recorded by Dr. W. Cayley[8] and may be mentioned here. The patient, a man, was suffering from alcoholic cirrhosis and ascites and was tapped four times. After the last tapping some symptoms of peritonitis appeared and the fluid did not again collect. He was discharged convalescent, a[illegible] dition is not known he was seen [illegible] his cab two years afterwards. [illegible] Dr. Cayley suggests the possi[illegible] exciting adhesive peritonitis as often happens in cases of ascites due to tuberculous peritonitis.

If the operation is to survive it must be shown that it possesses some distinct superiority over tapping, since, notwithstanding the slight risk of abdominal explorations, it is in every way more formidable than tapping, and it must always be remembered that many of the cases which require it are neither good subjects for operation nor for an anæsthetic.

From what has already been said it will, I think, be gathered that the cases best suited for operation are those in which the ascites is only an associated condition of the cirrhosis. The presence of cirrhosis is, of course, not by any means necessarily a contra-indication, but the further advanced the cirrhosis the less chance must there be of the operation being successful, and if there is good reason to believe that active symptoms of cirrhosis have supervened and that the ascites is directly dependent upon them the operation should not be undertaken, for at this stage, putting the cause of the ascites on one side, the liver is nearly always in such a condition as to be incompatible with prolongation of life. There must, of course, often be great difficulty in deciding whether the cirrhosis is still latent, and to this end the most careful attention must be given to the general condition of the patient and any signs that may denote that the liver-cells are not performing their functions well. Errors, however, will be further eliminated by selecting only such cases for operation as have been tapped several times, and so looking upon the operation as one likely to relieve some cases of ascites associated with cirrhosis of the liver, and not as one directed towards the actual liver condition itself; but the operation should not, it seems to me, ever be substituted in the first place for the more simple method of removing the fluid by tapping.

A RARE FORM OF PURPURA COMPLICATING DIPHTHERIA.

By CHARLES W. BUCKLEY, M.D. LOND.,
LATE ASSISTANT MEDICAL OFFICER TO THE SOUTH-EASTERN HOSPITAL, METROPOLITAN ASYLUMS BOARD.

A GIRL, aged 10 years, was admitted to the South-Eastern Fever Hospital on Oct. 8th, 1900, for diphtheria, it being the fourth day of the disease. There was membrane covering both tonsils and uvula, and a pure culture of Klebs-Löffler bacilli was obtained on cultivation. A large dose of antitoxin was injected. On the seventh day from the onset the throat was clean, but a raw surface remained where the membrane had separated. In the evening, however, the patient vomited and this recurred at frequent intervals throughout the next 36 hours; there was blood in the vomit on several occasions and one stool was passed containing a small amount of blood. Next morning a rash was noticed on the elbows, large papules of a deep purple colour, and there were numerous petechiæ on the buttocks. The heart was not dilated and the sounds were good but the pulse became very weak towards night and the patient was much exhausted by the continued vomiting. Next morning the vomiting had ceased, the pulse was better, but she was in a state of extreme exhaustion. Fresh petechiæ had appeared on the elbows, knees, and ears, and also over the malar bones, where they were large and well marked. The following day the rash on the elbows was seen to be becoming vesicular, fresh petechiæ had appeared on the buttocks, and there was a purplish mottling of the legs and feet. The vesicles on the elbows became confluent and formed large bullæ filled with dark, broken-down blood, and fresh vesicles appeared on the ankles. The bullæ were opened and dressed. The petechiæ on the buttocks and ankles were now very numerous, and the patient complained of stiffness of the elbows and inability to move them, but there was no pain when at rest—this was on the fifth day from the commencement of the vomiting. The tongue was dry and coated, the spleen was not enlarged, and there were no abdominal symptoms; the urine contained a trace of albumin. No definite change could be discovered in the blood on microscopical examination, but a blood count could not be made. On the next day there were pain and tenderness, but no swelling, of both elbows and the left hip-joint; the petechiæ were disappearing from their original sites and the bullæ were healing, but fresh petechiæ were noticed on the forearms. An erythematous rash with a few patches of urticaria of the type common after the use of antitoxin developed and became more marked after a few hours and the left hip-joint was noticed to be slightly swollen and painful, while over the front of it there were a few small ecchymoses. There was still a trace of albumin in the urine and on this day there were two stools containing blood to the amount of seven ounces altogether and during the night two ounces more were passed, while there were ecchymoses over the posterior iliac spines, probably due to the bed-pan. The abdomen was tender but the spleen was normal and also the heart and the patient was taking milk freely. The pain in the joints disappeared and there was no marked anæmia. The following day—the ninth from the onset of vomiting—she vomited twice, curds but no blood. Almost all traces of the original rash had gone except on the elbows, but a fresh crop of petechiæ appeared on the forearms and hands. There were also three small swellings over the bones of the forearms which were rather tender, but otherwise she had no pain. The cardiac dulness extended from mid-sternum to one finger's breadth internal to the vertical nipple line, and a very slight systolic murmur was audible just internal to the apex. On the eleventh day there was again a small amount of blood in the stools which were green in colour, having been black for several days. Next day a small ecchymosis was noticed on the left forearm, and a slight painless swelling on the flexor surface of the right forearm. The patient was much brighter and she felt hungry so some solid food was given for the first time since the vomiting set in. Good progress was made for the next 10 days, when the heart dulness was found to have increased as far as the nipple line on the left side. The first sound was weak and toneless and the pulmonary second sound was much accentuated, but after another 10 days the dulness was normal and the sounds were good, so she was allowed to sit up for the first time. On Nov. 19th, 40 days from the initial vomiting, she again vomited three times; the breath was foul, and there were scattered points of deposit on the tonsils, but there were no diphtheria bacilli found on cultivation. The temperature was 100·4° F., the highest recorded since the onset of the diphtheria. On the 21st a sudaminal rash appeared on the trunk, but there was no sign of purpura. The throat cleared up and there was no further vomiting. The cardiac dulness was now from the right sternal margin to just within the left nipple line; the first sound at the apex was weak and the pulmonary second sound was accentuated. This remained unchanged for three weeks, when a faint systolic murmur was detected at the apex conducted for a short distance beyond the nipple. The murmur gradually became less and finally disappeared, the cardiac dulness returned to its original limits, and the patient was discharged on Jan. 1st, 1901, as cured. Throughout the attack the temperature varied from 97° to 99°, rarely going higher and never above 100·4°, which was recorded on the occasion of the attack of tonsillitis. There was no history of any previous attack of similar nature or of rheumatism.

Remarks.—On consideration of the symptoms I think that there can be no doubt that this was a case of Henoch's purpura, although in some features it resembled rheumatism. Henoch describes the condition to which his name has been given as a form of purpura accompanied by colic, tenderness of the colon, vomiting, intestinal hæmorrhage, and rheumatoid pains. He also states that one of the links in the chain of symptoms may be absent and that it is characteristic that the symptoms come on in separate outbreaks with intervals of several days or weeks or even a year. Fever is not invariably present and is generally only moderate in degree.[1] All these features were present in the above case; the abdominal tenderness was never very marked, but the vomiting was extremely severe and the purpura was very well marked. The question of rheumatism must be considered, but such extensive purpuric manifestations are rare in that disease, although cases have been recorded.[2] The arthritic symptoms were quite a minor feature and did not resemble rheumatism in its usual form. The cardiac dilatation which might be attributed to rheumatism is even more characteristic of diphtheria. One of the most important points against rheumatism is the almost complete absence of pyrexia; the tonsillitis, which might be regarded as rheumatic, is an interesting feature, but was only slight and was not accompanied by any arthritis, while it is occasionally met with in convalescence from diphtheria without any other complication. On the whole, therefore, I consider that rheumatism may be excluded. Henoch states that he never found any marked changes in the blood and he was inclined to attribute the condition to a vaso-motor neurosis. Zimmerman[3] has described changes in the blood vessels chiefly affecting the media and adventitia, and other authorities have made similar observations in severe cases. Conty[4] holds that Henoch's purpura is of nervous origin and the concurrence in this case with diphtheria is very interesting in view of the marked influence of diphtheria on the nervous system. At the onset of the vomiting I was inclined to think that it was due to cardiac paralysis, but with the appearance of the purpura which was very different from that seen in the hæmorrhagic form of diphtheria, this view was abandoned. Whether the diphtheria stood in any causal relation to the other condition is a question which I am unable to answer.

The relation of the antitoxin administered may be questioned, but many other cases were injected with the same batch and in none did any of the above symptoms appear. The arthritis might be attributed to the antitoxin and it was practically concurrent with the typical antitoxin rash which appeared. It lasted, however, longer than antitoxin pains usually do and appeared to be due to some slight effusion into the joints rather than to be in the fibrous structures surrounding the joints as is usually the case with antitoxin joint pains. I am personally inclined to think that they were due to hæmorrhages into the joints, the conspicuous features being stiffness and tenderness rather than pain; the swellings over the bones of the forearms were probably subperiosteal hæmorrhages, while the swelling on the flexor surface of the forearm may have been due to hæmorrhage in or between the muscles or to a transient œdema such as has been described in similar cases. *The condition is a very rare one.* Henoch[5] describes eight cases as occurring in his clinic from 1868 to 1887, while Osler records 11 cases.[6] The prognosis appears to be fairly good. Of Henoch's eight cases six recovered, while Osler had three deaths in his 11 cases. Most of the fatal cases have been due to acute nephritis. The treatment adopted in the case under notice was complete rest with milk diet until all gastro-intestinal symptoms had subsided. The joint pain [illegible] pyrin and [illegible] arsenic, a[illegible] Dr. F. M. Turner, medical superintendent of the South-Eastern Hospital, for permission to publish this case.

THE DECIDUOUS DENTITION AS A FACTOR IN THE HEALTH OF THE CHILD.[1]

BY W. H. DOLAMORE, L.R.C.P. LOND., M.R.C.S., L.D.S. ENG.,

DENTAL SURGEON TO THE LONDON HOSPITAL AND ASSISTANT DENTAL SURGEON TO THE DENTAL HOSPITAL, LONDON.

THE consideration of this question groups itself under three headings: (1) the influence of the deciduous teeth on the general health during their eruption; (2) the important part which they play in assisting the nutrition of the child; and (3) the diseases, local and general, which may be induced or increased by them when they have become carious. In a paper it would be impossible to enter fully into a consideration of the whole of these points. I do the more readily confine my remarks to a general argument, since we may hope to hear the opinions of those among us who are so amply qualified to give us authoritative statements on all concerning the health of children. Thus, for instance, the infantile diseases associated with the eruption of the deciduous teeth do not as a rule come under the notice of the dental surgeon, but it would be interesting to hear opinions as to how far these troubles may be looked upon as due to the difficult eruptions of the teeth—whether they are merely coincident phenomena or whether they themselves may be the existing cause of the delayed eruption, the disease interfering with what in the normal state should be a painless physiological process. It is, however, interesting in this connexion to recall the fact that the date of the eruption of the teeth is somewhat variable, at all events in children of so-called civilised races. It is not an uncommon event to find successive groups of teeth erupting without that intervening period of rest which is laid down as the normal physiological course. This, doubtless, may be regarded as an expression of an abnormal systematic condition; nevertheless, it may in itself be a sufficient factor to determine various reflex or other pathological conditions. Thus in one child of the age of about 18 months the development of fits of an epileptiform nature was coincident with the eruption, not only of the four canines, as is normal at that age, but with that of the four second molars, which should not have appeared till six months later. The eruption of eight teeth coincidently would appear to have been the possible cause of the convulsions. Though, of course, why four molars erupted [illegible] lained.

[illegible] be better to take the part played [illegible] intaining the health of a child, before considering the constitutional effects which this may have when diseased, yet, in inverting the sequence, I perhaps strengthen the force of my argument, since reflection on that which we have lost is more pregnant with good intention than is the contemplation of that which we possess. Ignoring those unhappy children who are born with teeth—blighted probably by stomatitic inflammation in utero—which are teeth but in name, useless, dwarfed, decayed, even necrosed from the very beginning, I assume that the teeth are cut in, at any rate, an approximately perfect state. During the earlier stages of caries of the teeth the constitutional effects are slight and perhaps transitory, though in a delicate child the pain on attempts at mastication may lead to a refusal to take any but the softest food which might possibly not be without its permanent effect. But caries is, almost without an exception, progressive—not only leading to exposure of the pulp in a particular tooth, but spreading to other teeth, including those of the permanent series, owing to the acids formed by the decomposition of the food which collects in the cavities of decay. Moreover, although the vessels of the pulps of the temporary teeth do not become so quickly plugged, owing to the larger size of the apical foramina, as they do in permanent teeth, yet the septic inflammation which must necessarily ensue when the pulps are exposed will inevitably in time cause their death. The septic condition of the mouth now becomes worse, for to the previous factors there are added the breaking up of the gangrenous pulps and the collection of food in the pulp canals, where it remains free to decompose, unreached by the tongue or the ordinary cleansing processes, whether of the brush or the mastication of food or the drinking of fluid. Moreover, either by the direct spread of the inflammation or by the forcing of virulent septic organisms through the apical foramen, by the piston action of a plug of food forced into the tooth cavity, acute inflammation in the surrounding tissues may directly follow. But even supposing this may fortunately not happen the periosteum of such a tooth is almost always chronically inflamed, as is frequently seen when it is removed. Certainly so long as the pulp is not exposed, probably so long as an exposure does not lead to any extensive disease of it, no germs or germ products will be absorbed into the blood stream, but when the pulp is dead this inevitably happens to a greater or less degree.

The extremely foul condition of the mouth is readily apparent at the slightest glance, and I have been struck with the fact that in almost every case of ulcerative stomatitis which I have seen this condition of the mouth has been present and was, in my opinion, at least the predisposing cause. So, too, necrosis of the jaws as a direct sequel of abscesses under temporary teeth is quite common, especially in the neglected children of the poor. This is more frequently limited in extent, but it may be extensive. Thus in a case which I have recorded the sequestrum included the whole of one side of the mandible, including the coronoid and condylar processes. These conditions, though obviously not without their constitutional influence, are happily chiefly local in their effects and transitory in character, but sometimes these are permanent. Thus, in the case alluded to the boy enters on life handicapped by the loss of half of his entire dentition as the result of neglect of a temporary tooth. Apart, however, from those more or less local conditions the septic condition of the mouth has a marked influence in producing disease in other parts of the body. *Take, for instance, the lymphatic system.* Diseased teeth are universally recognised as one of the main factors in causing enlargement of the cervical glands and these again in turn are known to afford a nidus for the growth of tubercle germs whence they may spread through the whole body. The spread of tuberculosis is now occupying many minds, but hope rather fastens on preventative than on curative measures. Is it not important, therefore, that predisposing causes should be eliminated, and with these diseased [illegible] outh is an exciting [illegible] It is appalling to [illegible] which must in the course of a short time pass from the mouth into the stomachs of those numerous little ones of whose temporary teeth scarcely one is free from caries. The part played by a septic mouth in connexion with gastric troubles of adult life has long been known, but has lately been more prominently brought into notice by recent writing. Surely in children the effect must be equally great.

It would be possible to enlarge on this question very considerably—to mention other diseases, such as reflex nervous disorders, and to show by statistics how prevalent are carious teeth not only in the poor but in the rich, but I will now attempt to show, by considering the part played by the deciduous dentition in the health of the child, that the *remedy for diseases* caused by these teeth is not their extraction when carious, but rather the prevention of caries and the treatment of carious cavities while they are yet small.

The teeth in the deciduous set are functionally active between the ages of two and 10 years. Before the age of two years, though some are in place, the diet of the child is usually such as to require little mastication. Between the ages of seven and nine years the temporary incisors will have been exchanged for those of the permanent series, but these are only of secondary importance in the mastication of food. It is true that at about the age of seven years the deciduous molars will have been reinforced by the first molars of the permanent series, but these teeth, from the point of view which I wish to present to you, might even be considered as being for the time members of the temporary series. So that for this period of eight years the important part which the mastication of food plays in the nutrition of the child may be taken to be dependent on the temporary teeth. During the next two years the temporary molars are exchanged for their permanent successors; nevertheless, this is usually accomplished with but little impairment of the grinding surface available, for the first permanent premolars usually antagonise and are in use before the second temporary molars are lost. A little later than 12 years of age the second permanent molars erupt and thenceforward the child has available the full permanent dentition, excepting the wisdom teeth, the arrival of which is too erratic to enter into calculation.

---

[5] Lectures on Children's Diseases.

[6] American Journal of the Medical Sciences, 1895.

[1] A paper read before the Harveian Society on May 2nd, 1901.

If now the growth of the child during the period from two to 10 years of age be compared with that during a like period of eight years, from 10 to 18 years of age, the absolute need of the child having proper nourishment would seem to be strikingly manifest. Thus according to the report of the Anthropometric Committee published in 1883 during the first period the average male child increases in height 18 inches and a female child 18¾ inches; during the second period the male child grows 15¼ inches and the female child 10½ inches. These figures give the ratio of the two periods for the male child as 75 are to 61, and for the female child as 75 are to 42. Thus the period of most active growth of the bones is coincident with the functional activity of the deciduous teeth. If they are diseased or if they are removed, as is often most unnecessarily done, must not this be fatal to the proper nourishment of the child? The strain on the tissues during this period of growth would seem to be emphasised by the comparatively slight increase in weight of the child during the first period as compared with that during the second period. Thus, the above-mentioned tables give for the male child an increase of 2 stones 7 pounds for the first period and of 5 stones for the second period, whilst the female child increases 2 stones 8½ pounds in the first and 4 stones 3 pounds in the second period.

Without wishing to endeavour to prove too much by statistics, which someone has described as lies in the superlative degree, the fact that during the first period a female child growing 18¾ inches only increases in weight by 36½ pounds, whilst when growing 10½ inches in the second period she gains 59 pounds, would justify the inference that her nutrition during the first period was not in excess of her absolute need.

The importance of teeth is happily receiving more attention than was formerly the case. Recently a committee of the British Medical Association was appointed to inquire into causes of the prevalence of carious teeth. It was suggested by Mr. J. Cantlie, who moved the appointment of this committee, that something was radically wrong with the method of feeding children. Now whatever effect this might have on the permanent teeth the influence on the temporary ones, which alone I am considering, would be but slight, for the crowns of these teeth are already formed at birth and subsequent feeding, &c, could have little influence except on the outermost layers of enamel which remain to be deposited. It follows, therefore, that if these teeth are so to be formed that they will present no defects and will hence not become carious the habits and dietary of the mother, indeed of the whole community, must be radically changed. This may not be impossible, perhaps, but it is improbable. Hence it is important that the means at hand for preserving these organs should be taken advantage of. First and foremost the teeth should be cleaned regularly and thoroughly twice a day, nor can this be begun too early; if an infant has only one tooth that tooth will be the better for cleaning. Secondly, they should be periodically inspected and small holes when present should be filled. A child who has not suffered the pity of a misguided parent has no dread of the process, and this for small cavities is painless.

Though the means of prevention are thus in normal cases simple and easy we cannot, I fear, hope to see their adoption in the case of the children of the poor until we can convince school authorities that dirty teeth are more to be objected to than many other things, say, ink-spots on the fingers which are so hateful to the scholastic mind.

By a consideration of the effects of the teeth when diseased and of the importance of the teeth in the normal physiological growth of the child I have endeavoured to make good the argument that "the deciduous dentition is an important factor in the health of the child."

Queen Anne-street, W.

TUBERCULOSIS OF THE CHOROID.[1]

BY GEORGE CARPENTER, M.D., M.R.C.P. LOND.,
PHYSICIAN TO THE EVELINA HOSPITAL;
AND
SYDNEY STEPHENSON, M.B., F.R.C.S. EDIN.,
OPHTHALMIC SURGEON TO THE EVELINA HOSPITAL.

EVERY practical physician is aware that tubercle may now and then be found in the choroid of patients suffering from acute miliary tuberculosis. The diagnostic importance of these small bodies has been touched upon by all systematic writers. There is, however, no general agreement either as to the ophthalmoscopic forms which they may assume or as to the precise conditions under which they may occur. These omissions are doubtless due, first, to the technical difficulties attending an ophthalmoscopic examination of a young child with such a serious disorder as tuberculous meningitis, and, secondly, to the fact that a single observer, be he physician or be he ophthalmic surgeon, is scarcely likely to come across many cases of choroidal tubercle. It is our present intention to record our personal experience of tubercle of the choroid, and in doing so we shall purposely limit our remarks to what we have ourselves observed.

The following observations are based upon the study of 49 cases of tubercle of the choroid. They may be grouped as they were met with clinically in (1) acute miliary tuberculosis and tuberculous meningitis; (2) chronic tuberculosis, medical and surgical; and (3) obsolescent tuberculosis.

1. ACUTE MILIARY TUBERCULOSIS AND TUBERCULOUS MENINGITIS.

Out of 42[2] unselected cases of these diseases which we examined with the ophthalmoscope we found 21 with tubercles of the choroid, or exactly 50 per cent. In 13 of these cases tubercle was recognised in one eye only, and in both eyes in the remaining eight cases. This gives a total of 29 eyes (13 single and eight bilateral) in which the changes of tuberculosis were detected. In 18 of the eyes the lesion was solitary in the sense that it consisted of a single tuberculous deposit. In the remaining 11 eyes the number of separate lesions ranged from as few as 2 to as many as 12; but we desire to emphasise the fact that the common number was merely two or three. The tubercles usually took the form of round, oval, or reniform areas, of a fawn, grey, or paper-white colour. Their edges, which are perhaps best described as "moth-eaten" in appearance, were generally marked by a narrow zone of darker colour, due (as our microscopical specimens show) to local aggregation and proliferation of the retinal pigmented epithelium. The amount of pigmentation appeared to bear some relationship to the size of the tubercles, since it was generally absent from the smaller nodules, so that the latter could not well be distinguished by their ophthalmoscopic characters from any other choroidal exudation, such as may be met with in syphilis, acquired or inherited. Flecks, dots, or rings of pigment, doubtless of retinal origin, were occasionally to be seen upon the surface of the nodule itself. One of the tubercles was bounded by a pigmented ring with a halo outside it of scattered granules of dark pigment on a grey ground. It is important to note, however, that the tuberculous nodules were never framed, as it were, by a thick border of pigment, such as is commonly present in the lesions of an ordinary [illegible] illis. In one case [illegible] axis of the tuberc[illegible] centre of the littl[illegible] vessels, such as [illegible] to be present in some of our microscopical specimens. In three cases the tubercle assumed the rather unusual form of a small, oval granular, pigmented mass situated near the optic disc. In one instance a paper white tubercle was surrounded by a pale red ring, presumably due to congestion of the neighbouring choroid. The centre of some of the tubercles was marked by a tiny, white, shimmering dot, difficult to describe exactly in words. The retinal vessels when in immediate relationship to the tubercle (as they often were) passed over the nodule without loss of definition, as would be expected from the position of the lesion—namely, in the parenchyma of the choroid coat. In one case only was the slightest alteration noted in the neighbouring retinal vessels, which presented an ill defined muddy appearance, possibly due to localised œdema of the retina. In eyes where the choroidal vessels were unusually distinct these were seen to terminate abruptly at the edge of the tuberculous lesion. Judging by the position of the retinal vessels the tubercles were seldom much raised above the level of the retina. With regard to the size, the tubercules ranged from a fraction of a millimetre to three millimetres in diameter, and it was exceptional for them to equal the optic disc in magnitude. Practically speaking, they were found only in the immediate vicinity of the optic disc and the macula lutea—that is to say, in the so called "central region" of the fundus oculi. A peripheral distribution was noted only in cases where the tubercles were numerous with one exception. In a few instances the nodules lay exactly at the macula lutea. Thus, a small but definite tubercle was found in that position in one eye of a child aged five years whose second eye showed several small growths disseminated through the choroid. The patient died from acute miliary tuberculosis 10 days after the discovery of the choroidal lesion, and the nature of the ocular growth was confirmed both pathologically and bacteriologically. In another child, aged five years, a tubercle was found at each macula lutea. A third case was so unusual as to merit a few words of separate mention. A rickety boy, aged two years and five months, suffered from whooping cough, bronchitis, and an enlarged spleen. In the macula lutea of the left eye was a raised quadrangular mass about eight times the size of the optic disc of a dirty grey colour and with an ill defined margin. The retinal pigment was distributed irregularly over its surface. Those retinal vessels which crossed the area were blurred owing, we presume, to œdema of the retina which had been detached by the underlying tubercle. The child succumbed to general tuberculosis six weeks after the eyes were examined and at the necropsy a large grey tubercle was found at the macula lutea.

---

[1] A paper read at the provincial meeting of the Society for the Study of Disease in Children at Liverpool, June 29th, 1901.

[2] Of 36 cases of general tuberculosis, all except six of which were verified by necropsy, 28 had head symptoms. There were six cases of tuberculous meningitis, four of which were verified at the post-mortem examination. Of the total number of cases (42) 16 developed optic papillitis.

There is an impression that tubercles of the choroid visible with the ophthalmoscope may appear in the course of a few days or hours. The only evidence which we possess on this point was furnished by a child, aged five years, with coarctation of the aorta whose fundus oculi was examined with negative results on June 10th 1895. Nine days later however, a further investigation revealed the presence of three small tubercles near the optic disc of the right eye. A statement which apparently rests on the authority of Cohnheim has been made that choroidal changes are commoner in tubercle without than with meningitis. Our present figures lend no support to this generalisation, as may be seen on referring to Note 2. Is tubercle of the choroid a late symptom? We find that the period elapsing between discovery of the ocular changes and death ranged in 14 fatal cases from one to 43 days. We conclude therefore, that it is not necessarily a late symptom of general tuberculosis. The following case, indeed shows that choroidal tubercle may be an early sign. A boy, aged three years, with cervical caries was examined on April 24th, 1890 and was found to have a solitary tubercle near the yellow spot of the right eye. He developed whooping cough in the early part of 1891 and died from general tuberculosis (confirmed post mortem) at the end of April in the same year.

From the foregoing remarks it will be obvious that in acute miliary tuberculosis and tuberculous meningitis choroidal tubercle may assume several different forms. It is important to remember that in a majority of the cases the lesion in the choroid is small, single, and limited to one eye. This emphasises the somewhat obvious fact that both eyes must, as a matter of routine, be examined before the absence of choroidal tubercle can be affirmed.[3]

Our figures prove that choroidal changes are frequently present in acute tuberculosis. Indeed, in our opinion, they form perhaps the most trustworthy sign of that disorder, the diagnosis of which as we all recognise, is often most obscure. Attention is sometimes drawn to a discrepancy between the alleged infrequency of the ophthalmoscopic discoveries, on the one hand, and the frequency of the pathological findings, on the other. Admitting the truth of this view, which, in the light of our present figures, we do with some little hesitation, there are several points to be borne in mind. Tubercle, although present, may lie in the anterior portions of the choroid coat beyond the range of the ophthalmoscope, as we have ourselves found. If the nodule is not large enough to cause disturbance of the overlying retinal pigmented epithelium it can scarcely be visible with the ophthalmoscope although it may be found on post mortem inspection when the retina is removed. It seems likely that the rapid appearance of fresh tubercles mentioned by many writers is to be explained by an acute disintegration of the pigmented epithelium rather than by a presumed unusually sudden appearance and rapid growth of the nodules themselves. Then there remains, last but not least, the personal factor which is certainly not without influence when it comes to examining the eyes of a young and troublesome child with the ophthalmoscope. In short, we repeat that careful ophthalmoscopic examination will show tubercle of the choroid to be quite common in acute miliary tuberculosis, since it was present in 50 per cent. of our cases.

2. CHRONIC TUBERCULOSIS, MEDICAL AND SURGICAL.

We have examined with the ophthalmoscope 119 cases of chronic tuberculosis in children whose ages ranged from eight months to 16 years. They suffered from such various affections as tuberculous joints, chronic tuberculous adenitis, spinal caries, chronic tuberculous cerebral tumour (two cases), and lupus. Amongst them we found choroidal changes in no fewer than 11, or 9.24 per cent., of which three were verified post mortem. The choroidal lesions fell into four groups—viz., (1) the solitary, (2) the multiple, (3) the disseminated, and (4) the diffused. As the solitary and the multiple closely resemble those already described in acute tuberculosis they need not be further particularised. The case of disseminated tubercle of the choroid occurred in a stunted lad aged 12 years, with extensive scrofuloderma and chronically enlarged cervical glands. He showed absolutely no signs of hereditary syphilis. Both eyes presented a condition indistinguishable from choroiditis disseminata syphilitica. The evidence, however, pointed clearly in the direction of a tuberculous and not a specific origin for the choroidal mischief. The case of diffused tubercle was in some respects even more remarkable. A boy, aged six years and seven months came under our notice on April 21st 1901. His right eye had been "blind" for about 18 months and he had suffered from tuberculous arthritis for about eight months. There was no family history of phthisis, but a lodger with that disease had lived in his parent's house before the onset of the eye trouble. We found the lad suffering from tuberculous arthritis of the right knee and slight chronic enlargement of the cervical glands. There was no evidence whatever of syphilis. The fundus of the right eye manifested extensive changes. There were visible large areas of detached retina probably caused by gross masses of tubercle in the choroid. Glistening white smaller patches (which resembled roughly those of albuminuric retinitis) possibly represented tubercle of the deeper layers of the retina. In rare cases diffused tubercle may assume even greater dimensions. A youth, aged 16 years, gave a family history of phthisis on his mother's side. He himself suffered from a cough and presented signs of tubercle at one apex. His right eye was blind and painful. The cornea was diffusely hazy. The tension of the globe was raised. No reflex could be obtained from the fundus. The eye was excised as probably containing a tumour of tuberculous nature. Upon examination the vitreous chamber was found to be filled with a greyish solid exudation with a lenticular shaped hæmorrhage at one part. Microscopically the exudation was found to consist of caseous material staining very imperfectly. Bacilli were not looked for. Such a case as this in a child under three years of age would be difficult or impossible to distinguish from glioma of the retina.

---

[3] We may add that in our experience the best way is first, to scrutinise the fundus oculi by the indirect method for the purpose of discovering the lesions and then having found them to work out their exact details by the direct method. A pupil dilated with euphthalmine or some other mydriatic agent is almost indispensable for the average observer and a great help even to an expert.

Finally, we quote one case to show the diagnostic value which may attach to the discovery of these choroidal changes. A boy, aged four years, was brought to the hospital with paresis of his right side and especially of his right leg. There was double optic atrophy, and in one eye a small paper-white tubercle was found close to the optic disc. The provisional diagnosis of a tuberculous cerebral tumour was made. The child soon afterwards developed Jacksonian epileptiform convulsions, became comatose, and died from exhaustion. A large tuberculous tumour was found to occupy the upper two frontal convolutions on the left side of the brain and to press upon the ascending frontal convolution. We venture to think that a positive diagnosis could not have been reached in this case had a choroidal tubercle not been discovered.

3. OBSOLESCENT TUBERCLE.

In examining eyes systematically one sometimes comes across unsuspected changes of a coarse character which are far more likely to be due to quiescent tubercle than to anything else. In the absence of a pathological examination it is, of course, impossible to be dogmatic on the point, but the family history and the physical examination of the cases render such an explanation something more than merely probable. We have notes of 16 such cases, of which one or two of the more typical may be briefly cited. In the first case which we quote a boy, four years of age, had chronically enlarged glands, a thickened upper lip, and running and excoriated nostrils. There was a family history of phthisis. A quadrangular area, somewhat larger than the optic disc, was present in the macular region of the left eye. Its colour was lighter than that of the surrounding fundus. The centre of the figure was marked by a small mass of pigment, and this was encircled at some distance by a pigmentary ring, the intervening area having a greenish-grey hue. The periphery of the patch showed here and there slight accumulations of pigment. Several retinal vessels crossed the patch without being in the least involved. The only change observed during the six years that the lad remained under observation was a gradual increase in the density of the central pigmented ring. In another case a boy, aged four years, presented in the central region of the left fundus oculi an oval patch nearly as large as the optic disc. Its appearance was something like that of the case last mentioned. The child had enlarged cervical glands, but unfortunately his family history was unknown. In a striking case we met with the patient was a woman, aged 51 years, who gave a strong family history of phthisis. She had herself been treated at the Brompton Hospital for her chest some 30 years before coming under our notice. Lying near the inner side of the left optic disc was a circular area, half as large again as the optic papilla. It showed exposed choroidal vessels and was bordered by pigment. A number of tiny fawn-coloured spots—all, with one exception, devoid of pigment—were scattered about the fundus near the main lesion and the optic disc, and doubtless these represented satellite tubercles which had also become quiescent. A fine film was present in the vitreous tumour, but sight was normal. We have notes of 13 other cases, but we will merely say that the essential ophthalmoscopic characters of obsolescent tubercles in the choroid appear to us to be (1) their central position in the fundus oculi; (2) their large size and presence in one eye alone; (3) their characters—namely, a central atrophic area, inclosed by a pigmented figure, and often surrounded by a zone of altered choroid; and (4) the fact that they are sometimes associated with tiny atrophic spots in their vicinity, doubtless representing their former satellites. That they may assist diagnosis in some doubtful cases is shown by the case of a girl, aged 10½ years, who was seen on July 27th, 1886, with the history that she was healthy until two years of age when she developed convulsions which were succeeded by hemiplegia. Her father had died from phthisis. She had been treated at a children's hospital for "infantile paralysis." Upon examination she was found to have left hemiplegia and increased patellar and elbow jerks, but no facial paralysis. In her left eye was a patch of what appeared to be obsolescent tubercle of the choroid. This latter observation threw some light upon the nature of the lesion, and rendered it probable that the hemiplegia was due to a localised tuberculous growth in the brain.

SUMMARY.

1. Tubercle of the choroid may be met with in any form of tuberculosis, whether acute, chronic, or obsolescent. 2. It is common in acute miliary tuberculosis and tuberculous meningitis, since it was present in 50 per cent. of our cases. As a rule the lesion was of small size, solitary, and limited to a single eye. 3. It is far more frequent in chronic tuberculosis than is generally supposed. It was present in 9 24 per cent. of our cases. The tubercle in this form of disease may be single, multiple, disseminated, or diffused. In very rare instances it may attain great dimensions and eventually even perforate the tunics of the eyeball. 4. It is present in a certain number of cases of quiescent tuberculosis. It then generally takes the form of a large more or less pigmented area situated in or about the central region of the fundus oculi, with or without satellites.

NOTES ON SOME SURGICAL CASES TREATED IN THE GENERAL HOSPITAL AT SPRINGFONTEIN.[1]

BY S. F. LOUGHEED, M.D. R.U.I.,
MAJOR, ROYAL ARMY MEDICAL CORPS.

CASE 1. *Gunshot wound of the head; trephining.*—A trooper in Nesbitt's Horse, aged 19 years, was wounded near Phillipolis, O.R.C., on Oct. 22nd, 1900, at a range of 100 yards. When hit he was standing but fell in a minute or so; he then spoke a few words and was taken to an hotel where he remained in a semi-conscious state till the 25th. He then got up, dressed himself, spoke sensibly, and was taken in an ambulance to No. 12 General Hospital, Springfontein, a distance of 28 miles. During the journey he had fits which occurred about every 20 minutes, but was conscious in the interval. His condition on the 27th when he arrived at Springfontein was as follows. There was an entrance wound, apparently caused by a Mauser bullet, an inch posterior to a vertical line drawn from the apex of the left mastoid process to the centre of the fronto-occipital line and four inches above the mastoid apex. There was an exit wound three inches above the occipital protuberance and one inch to the left of the median line. The distance between the two wounds was two and a half inches and the scalp was not divided; no bare bone could be detected or fracture made out with a probe. He had complete motor paralysis of the right arm and leg and partial paralysis of the right side of the face. The knee-jerk was much exaggerated on the right side; it was normal on the left. He had motor aphasia; when asked a question he answered it, but not correctly. He had Jacksonian seizures commencing in the right side of the face and extending to the right arm and leg; they were very severe, lasting about three minutes. On the 28th he had six seizures; on the 29th, 30th, and 31st he had 10, 50, and 27 seizures respectively. On Nov. 1st operation was performed. Under chloroform the scalp was divided between the wounds and a vertical incision was made at the entrance wound three inches long. The periosteum was found to be intact and no fracture was visible. With a trephine a disc of bone was removed from beneath the entrance wound and this opening in the skull was enlarged upwards and forwards with Hoffman's gouge forceps. The dura mater was of a shining bluish colour, evidently from subdural clot. The dura was incised in a T-shaped manner and dark blood-clot at once protruded. It measured about two ounces and was cleared away. It came principally from the upper and anterior parts around the opening. The parts were well cleaned and the dura mater was closed with fine silk except at the centre of the T-shaped incision which was left open for drainage. A small drainage-tube was placed with one end over the opening in the dura mater and the other brought out to the most dependent part of the scalp incision. The scalp was united by silkworm gut and cyanide gauze dressings were applied. The patient slept for five hours after the operation and woke quite conscious, when it was found that he could move both the right arm and leg and he asked for food. On Nov. 2nd he had two seizures (Jacksonian). On Nov. 3rd he had six seizures; the wound was dressed and the tube was removed, cleaned, and replaced. About 8 P.M. he became very violent, having had little sleep for the past 24 hours, and chloroform was administered to him to induce sleep, which it did, and he slept soundly for eight hours, waking up perfectly conscious and rested. From this time he had no more seizures and made an uninterrupted recovery. The tube was removed on the eighth day and not replaced and the wound healed up without any further trouble. The power gradually returned to the right arm and leg and the face became normal. On Nov. 13th he was allowed to sit up, and soon regained both his former appearance and strength. On Nov. 20th he was walking about and had full use of his limbs; the knee-jerks on both sides were normal and his cerebral power was as before the injury. There was a slight depression over the trephine hole and there was visible brain pulsation. He was discharged from hospital on Dec. 20th to proceed to his relatives at Port Elizabeth for two months' furlough.

---

[1] We are enabled to publish these interesting cases through the courtesy of the Director-General of the Army Medical Service.

CASE 2. *Gunshot wound of the head; trephining.*—A private in the 9th Lancers, aged 23 years, service four years, was wounded near Dewetsdorp, O.R.C., on April 16th, 1901, when lying down. He was rendered insensible for 10 minutes but then recovered consciousness and found that he could not move his right arm. On arriving at No. 12 General Hospital, Springfontein, on the 18th his condition was as follows. He was quite sensible; he had complete paralysis, motor and sensory, of the right upper limb; both legs were intact and with normal jerks; both sides of the face were normal; he protruded the tongue straight; there was no ptosis; hearing and vision were normal. His temperature was normal; he had slight headache. He had a ragged scalp wound over the left parietal eminence two and a half inches in length, running horizontally over the centre of the Rolandic area. The bone was not bare and no fracture could be detected. The wound was two and a half inches from the inter-parietal or sagittal suture. No change occurred in his condition on the 19th, 20th, and 21st. Operation was performed on April 22nd under chloroform. An incision through [illegible] right angles and [illegible] was made. The [illegible] trephine was applied over the parietal eminence. A disc of bone was removed and a small hæmorrhage was found over the dura mater. The dura mater was divided by a T-shaped incision after the hole was enlarged backwards and forwards by Hoffman's gouge forceps. Fairly large dark clot, about four drachms, was found beneath. No fracture of either table could be found. The clot was removed with forceps and swabs. The dura mater was brought together with fine silk interrupted sutures except at the centre of the T with Hagedorn's curved needle and holder. A small drainage-tube was inserted, emerging from the most dependent angle, and the flaps were sutured together with silkworm gut. Gauze dressings were applied. On recovering from the chloroform he could move his right arm and had sensation in it. On the 23rd the arm could be moved well and he had complete feeling in it; the dressings were changed and the tube was shortened. On the 24th the tube was removed; the wound was perfectly aseptic; the temperature was normal. The patient slept well. The wound was dressed on the 26th and was doing well. All the stitches were removed on the 28th and the wound was closed except at one point. The wound was soundly healed on May 4th. No brain pulsation could be detected beneath the scar and the power in his arm had much improved. He was allowed to be up. He made a complete recovery and regained full power in the arm.

CASE 3. *Gunshot wound of the spine; laminectomy.*—A sergeant of the 1st South Lancashire Regiment was wounded at Kalfontein on Oct. 26th, 1900, and was admitted into No. 12 General Hospital, Springfontein, on the same date. On admission he had complete paralysis, motor and sensory, of both legs. The loss of sensation extended up to the level of the fifth ribs; respiration was almost entirely diaphragmatic. He had priapism, retention of urine, and incontinence of fæces. The knee-jerks were absent in both legs. He had an entrance bullet wound, probably caused by a Mauser, one inch to the right of the mid-sternum in the first intercostal space and an exit wound half an inch to the right of the fifth dorsal spine. His co[illegible] for some days, and as the directi[illegible] to the right of the median line [illegible] sidered advisable. Operation under chloroform was performed on Nov. 10th. An incision four and a half inches long was made in the middle line over the fourth, fifth, and sixth dorsal s[illegible] on both sides from the spines and laminæ. Three spinous processes were removed with cutting bone forceps. The lamina of the fifth dorsal was found to be fr[illegible] pierced by the b[illegible] disc of bone wa[illegible] dura mater had [illegible] underneath. No blood-clot was found or any trace of pus. The wound was closed with interrupted catgut sutures and again the dressings were applied. No improvement occurred in the man's condition. Bedsores had developed over the sacrum and his lungs were filled with mucous secretion. He died rather suddenly on Nov. 12th from cessation of respiration. Post-mortem examination revealed a wound of the apex of the right lung, some hæmothorax (about six ounces), and pus and mucus in the bronchial tubes. A hole was found in the right side of the body of the fifth dorsal vertebra and a director passed easily through it and the spinal cord to the trephine opening in the lamina.

CASE 4. *Gunshot wound of the right leg; amputation.*—A trooper in Nesbitt's Horse was wounded at Phillipolis, O.R.C., on Oct. 22nd, 1900, and was admitted into No. 12 General Hospital, Springfontein, on the 27th. The entrance wound was one inch below and outside the lower border of the right patella, extending downwards and inwards through the head of the tibia into a large cavity between the two bones of the leg. The bullet was lodged, there being no exit. His temperature was 102° F. and the wound was very septic. Suppuration continued with bagging of pus in the calf of the leg. Alarming secondary hæmorrhage occurred on the night of Nov. 3rd, and under chloroform the entrance wound was enlarged downwards into a large cavity in front and behind the inter-osseous membrane. The anterior tibial artery was secured by ligature but profuse bleeding continued from behind the inter-osseous membrane, consequently amputation through the lower third of the thigh was performed, as the knee joint was full of fluid which was found to contain pus at the operation. Amputation was performed after Carden's method above the synovial cavity with a long oval anterior flap, the hamstring muscles being divided transversely and the patella removed. The temperature remained normal for 48 hours and then went up to 102° F. The wound was irrigated through the transverse tube and redressed. The tube was removed on the fourth day; some stitches gave way at the inner angle. Fomentations were applied for a few days and [illegible] subsided. The wound took on [illegible] were brought together by antisep[illegible] wound healed with only a cicatri[illegible] between the skin edges and on Dec. 1st the man was up. He was transferred to the base on Dec. 7th, having a sound stump. A Mauser bullet was found in the calf.

CASE 5. *Gunshot wound of the left leg; amputation.*—A private in the 9th Lancers was wounded at Phillipolis on April 12th, 1901; his horse having been shot under him, he ran on foot and tried to escape. He was admitted into No. 12 General Hospital at 4 P.M. on the 15th, having been carried in an ambulance since he was injured. The entrance wound was about the centre of the calf of the left leg in the middle line; it was small and round. The exit was through the shaft of the tibia two inches below the tuberosity; it was large, ragged, and had bone spicules protruding from it. The fibula was also broken. A pulsating swelling was present below and outside the exit wound, which could be controlled by pressure over the femoral artery. Secondary hæmorrhage from the exit wound occurred at 5 A.M. on the 19th, and operation under chloroform at once was decided upon. Bleeding was controlled by tourniquet, and the anterior wound was enlarged up and down. An immense sac full of clot was found in front of the inter-osseous membrane, communicating with a similar one behind in the calf. Both tibia and fibula were shattered for about four inches. Bleeding from the anterior tibial artery was controlled, but that from the posterior tibial could not be got at owing to the small space between the bones. A Carden's amputation was then performed, leaving a good long anterior flap. The tissues on the outer side of the knee were much bruised and œdematous. A transverse tube was placed in the wound. [illegible] was examined and both tibial arteries [illegible] d more than 20 pieces of comminuted [illegible] The knee-joint was not opened into. The stump was dressed on the 21st; there was very little oozing and the wound was quite aseptic. The temperature was normal. The tube was removed on Oct. 22nd, 1900. One stitch gave way at the outer angle where the tissues were found damaged at the time of operation. The dressings were changed daily, the discharge being very slight, and the wound finally healed without any trouble. The stump was well covered and sound.

CASE 6. *Strangulated hernia; herniotomy; radical cure.*—A sergeant in the chief's bodyguard, aged 40 years, had had a right inguinal hernia for many years which he kept supported by means of a truss. He found on Dec. 4th, 1900, when at Bethulie, that he could not reduce it and suffered from pain. He was admitted into No. 12 General Hospital, Springfontein, on the 7th, and as it could not be returned by taxis operation was performed under chloroform on the 8th. The bowels had been completely obstructed since the 4th. An incision four inches long over the ring and neck of the sac was made and the tissues divided on a director; the neck of the sac was reached and the sac was opened; the finger was introduced upwards and the constricting neck was divided with a herniotome. The gut was much congested and collapsed but was considered fit to be returned, which it was at once. The whole sac was then separated from the cord and tied high up at its neck with twisted gut ligature; the part below the ligature was cut off and removed. The lower border of the internal oblique muscle was then stitched to the back of Poupart's ligament, the cord being brought out at the internal abdominal ring. The external oblique muscle, which had previously been slit up to allow of the neck of the hernial sac being divided, was then brought together by interrupted silk sutures, the cord also being brought through it over the internal abdominal ring. The cord then lay between the external oblique and skin which was united by horse-hair. Cyanide dressings, wool, and a double spica were applied. The patient passed flatus per anum on the evening of the operation. His temperature never went above normal. The skin stitches were removed at the eighth day (first dressing) and complete union had occurred. The bowels acted naturally on the third day after operation. The man was kept in bed for 21 days and then allowed up. There was a sound scar. There was no hernial impulse on coughing. It was a complete cure. He was discharged to his duty on Jan. 15th, 1901, having no trouble.

CASE 7. *Strangulated hernia; herniotomy; radical cure.*—A private in the 65th Company Imperial Yeomanry, aged 33 years, was admitted on May 4th, 1901, in No. 12 Garrison Hospital, Springfontein, with a strangulated right inguinal hernia which he stated came down at 1.30 the same day after his dinner; he stated that when he was a child he had some trouble in this region and wore a bandage for some time, but since then he had had no trouble from it or ever noticed any swelling in this region. On admission an elongated tumour of about the size of a large egg occupied the upper part of the scrotum on the right side; it was tympanitic and had an impulse on coughing, but could not be reduced by taxis. He had vomited many times and passed no flatus per anum since it appeared. He complained of twisting pains about the umbilicus. As the symptoms were not urgent an ice-bag was aplied. On the morning of the 5th the tumour was much smaller and by means of manipulation was slowly returned into the abdomen but without the characteristic gurgle of a successful reduction. The tumour could still be felt in the inguinal canal. He had pain, and vomiting during the day continued, and he passed no flatus. On the morning of the 6th, under chloroform, an incision similar to that for radical cure was made and after division of the fascia the tumour was found in the inguinal canal; the sac was opened and its constricted neck was divided; it contained a small knuckle of gut much congested and collapsed, but appeared capable of recovery and was at once returned into the abdomen. The sac was completely separated from the cord and its neck was tied high up at the internal ring with stout silk; it was divided below the ligature and removed. The cord was raised up and the internal oblique was united to the back of Poupart's ligament by six strong interrupted silk sutures. The external oblique was then united along its division, thus obliterating the inguinal canal completely, the cord having been brought through it opposite the internal ring. The cord then lay on the external oblique and under the skin which was united by horsehair interrupted sutures. This is the operation performed by the "Bassini-Halsted" method. Flatus passed on the evening of the 6th and vomiting and pain ceased. The bowels moved naturally on the 9th. The first change of dressings was on the 14th. The stitches were removed. The wound was quite healed. He made a complete recovery.

CASE 8. *Internal strangulation of the bowel; laparotomy; removal of a constricting band.*—A 1st Class Staff Sergeant, when playing cricket at Springfontein on Dec. 30th, 1900, felt a sudden pain in the middle of his back after delivering a ball. The pain spread to the front of the abdomen and he vomited. He was admitted to hospital and during the next four days he suffered from constipation, vomiting, and tympanitis. No flatus passed and no abdominal tumour could be made out. As the symptoms became urgent operation was performed under chloroform on Jan. 4th, 1901. A median abdominal incision six inches long from the pubes upwards was made and the abdominal cavity was opened. The hand was introduced towards the cæcum and the small intestine was drawn out and traced upwards. The withdrawal was soon stopped owing to tension and the hand again introduced towards the left iliac fossa. A thick constricting band was then found surrounding the ileum and binding it down to the brim of the pelvis on the left side. By a little manipulation this was easily broken through and most of it was removed by the scissors. It was rather friable and only semi-organised. Flatus at once passed through the obstructed spot with a marked gurgle. The intestines were washed with "boiled water" and returned without difficulty. A gauze pad was placed over the intestines and under the wound while the stitches were being introduced. Stout silk was used as the suturing material and the peritoneum, abdominal muscles, and skin were all included in the through stitches; before the last two stitches were tied at the pubic end of the wound the cyanide gauze pad placed on the intestines was withdrawn, thus leaving no blood in the abdominal cavity. Cyanide dressing, wool, and a many-tailed bandage were put on and the patient returned to bed with warm bottles around him. The patient recovered quickly from the shock, passed flatus per anum at 6 P.M. on the day of the operation, and did not vomit any more. The bowels moved naturally on Jan. 6th and the temperature never exceeded 99° F. at night. The wound was dressed on the 14th and all the stitches were removed; union was complete and without any suppuration. The action of the bowels continued normal. He was allowed up on the 25th and he made a complete recovery. He was sent to the base on Feb. 8th and is doing duty there at present date (May 11th, 1901).

CASE 9. *Inguinal hernia with atrophied and partly undescended testis; radical cure.*—A private in the Cape Medical Staff Corps, aged 22 years, was admitted to No. 12 General Hospital, Springfontein, on Feb. 20th, 1901, with a large left-sided bubonocele complicated with an atrophied, partly undescended testicle on the same side. The hernia was large and seemed to flatten out between the layers of the abdominal muscles; it could easily be returned into the abdominal cavity. The testicle at times came down into the upper part of the scrotum but usually lay in the inguinal canal just inside the external ring and was quite small and soft. He desired an operation and to retain the testis if possible. Under chloroform on March 1st a radical cure was performed; the sac was found to have a very large neck which was ligatured after transfixion with stout silk. The testis was very difficult to keep in the scrotum and its cord was much attenuated and without much vascular supply. The operation was performed after the "Bassini Halsted" method and the cord placed between the skin and external oblique. A pressure pad was placed over the occluded external abdominal ring to keep the testis from coming up out of the scrotum and the usual dressings were applied. No rise of temperature followed and the dressings were not changed till the eighth day when the testis was found to have slipped up and lay under the scar. Two stitches were cut and as the testis was quite dark in colour but aseptic it was removed through the wound by dividing its cord with a curved scissors, the wound was again closed, and dressings were re-applied. No suppuration followed and the wound gradually healed up completely and soundly. A thoroughly good result followed, as there is not the slightest attempt at a recurrence or any weakness of the abdominal wall at the site of the operation. He is since doing duty in this hospital and has had no recurrence.

CASE 10. *Inguinal hernia; radical cure.*—A private in the 16th Mounted Infantry, aged 24 years, was admitted into No. 12 General Hospital on April 15th, 1901, suffering from a large incomplete inguinal hernia which caused him much trouble in riding. The opening through which it came—viz., the internal abdominal ring—was very large. Operation under chloroform was performed on April 21st, 1901. A skin incision was made over the inguinal canal three inches long.

No sac was present, the peritoneum being quite smooth behind the internal abdominal ring, but a considerable space *existed between the lower border of the "conjoined tendon"* and Poupart's ligament, which was closed by seven interrupted strong silk sutures, bringing the cord out at the internal ring, the external oblique was then sutured from opposite the internal ring, where the cord was brought through, down to the spine of the pubic bone, thus obliterating th [illegible] kin was closed with horsehair [illegible] nployed The temperature kept n [illegible] changed on the eighth day and all the skin stitches were removed Union was complete. The patient was kept in bed for 21 days There was no impulse on coughing or other weakness of the abdominal wall There was a very good result He was sent to a convalescent camp before returning to duty

CASE 11. *Inguinal hernia, radical cure*—A lance corporal in the 17th Lancers, aged 25 years, was admitted to the No 12 General Hospital suffering from a large complete left inguinal hernia which, although he wore a truss, had been giving him much trouble in riding *The opening in the external oblique admitted two fingers* easily and there was a varicocele on the same side but not of large size, the veins along the cord being involved Operation under chloroform was performed on May 3rd, 1901 The usual skin incision and division of fasciæ down to the external oblique was made which was slit up parallel to its fibres from the external ring for about two inches The cord was then raised from its bed and its fascial coverings were removed, the sac was then separated from spermatic vessels and freed up to the internal ring, it was transfixed and ligatured as high up as possible It was then cut below the ligature and removed. The veins of the cord being numerous and bulky were separated into two parts, the smaller bundle, ligatured above the internal ring and below near the testes, was removed with the scissors, quite enough veins were left to carry on the circulation along the spermatic artery and vas deferens The operation was then completed according to the "Bassini Halsted method' already described and the usual dressings were applied No rise of temperature ensued except on the night of the operation, when it rose to 100 8° F., next morning it was normal and remained so till he recovered. The bowels were moved after a glycerine enema on the third day and his dressings were not changed till the ninth day when the wound was found thoroughly healed and the stitches were all removed from the skin

No 12 General Hospital, Springfontein

LICHEN FROM A HISTOLOGICAL POINT OF VIEW.

By MORGAN DOCKRELL, M D Dub,

PHYSICIAN TO ST JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, LONDON,
CHESTERFIELD LECTURER ON DERMATOLOGY

To all dermatologists the study of lichen is an interesting one, not only because of the obscurity of its etiology and the heated discussions that have arisen in connexion with its varieties, but also because of the number of clinical conditions lending themselves to that multiplication of qualifying terms which seem to be so dear to the expounder of the art of dermatology Whether this latter tendency originated in the desire to keep the knowledge of cutaneous disease in the hands of a few it certainly has had that effect, and much to the discredit of dermatologists it is the branch of medicine least known and understood by the great bulk of the medical profession That this is likely to remain so is certain unless those who have the opportunities of teaching dermatology decide to take their responsibilities seriously and to substitute for the dross of a confusing nomenclature the sound practical value of instruction in the microscopical appearances which correspond to the clinical conditions which they demonstrate. When this is more universally done we shall be spared discussions serving only the purpose of making confusion worse confounded without advancing science in the very least.

If the history of lichen be examined one finds that ever since the writing of Hippocrates, jun, it has been admitted that a lichen must be a papular disease, although from time to time a pustule seems to have been added as part of the lichenoid condition Willan, however, recognised the condition as being only a papular one and classified lichen into the following varieties simplex, pilaris, circumscriptus, agrius, lividus, and tropicus, to these were subsequently added *hæmorrhagicus*, strophulus, circinatus, gyratus, syphiliticus, spinulosus, and scrofulosus. Fortunately all these varieties have been included in other conditions and so got rid of However, in 1860 Hebra described a disease which proved very fatal, and he called it "lichen ruber" A little later Erasmus Wilson described the condition known as lichen planus, but subsequently he came to the conclusion that the disease which he described was the same as that described by Hebra. In 1873 Tilbury Fox identified both as modifications of the same disease, and four years later Kaposi, with Hebra's consent, classified the terms "lichen ruber" and "lichen planus,' and called the two diseases "lichen ruber acuminatus" and "lichen ruber planus"

It was next asserted by the French school that the pityriasis rubra pilaris described by Devergie in 1857 was the same as the lichen ruber acuminatus, and to this Kaposi seems to have agreed Others have asserted that Hebra's original description arose from confusing the three conditions, lichen ruber acuminatus, generalised lichen planus, and pityriasis rubra pilaris but even so this hardly accounts for the fatal cases described by Hebra as lichen ruber It seems quite unnecessary to trouble further about these cases of Hebra; the only living link between Hebra's cases and the present is Kaposi and he has declared for the identity of lichen ruber and pityriasis rubra pilaris In order to solve this question I commenced a research some 12 months ago, and the result of the investigation has been to convince me (1) that pityriasis rubra pilaris is different clinically and histologically in a well marked manner from lichen, (2) that the so called lichen rubra acuminatus and lichen ruber planus are the first two stages of a disease now known as lichen, (3) that the planus stage is always preceded by the acuminate, although often the patients do not come under observation till the planus stage is established, (4) that the disease when it becomes chronic may pass on to the hypertrophic stage or even to a higher stage still—the verrucose, (5) that clinically and histologically lichen presents four easily traceable stages of transition from the early acuminate papule to the densely thickened infiltrated patch of the verrucose condition, and they are known as (*a*) the acuminate, (*b*) the planus, (*c*) the hypertrophic, and (*d*) the verrucose, and lastly, that neither the hair follicles nor the sweat glands are primarly involved, and only become secondarily so in the third and fourth stages It will be, perhaps, most convenient if I take the clinical and histological features of pityriasis rubra pilaris and then of each stage of lichen, so as to demonstrate in the first place and, I hope, finally that there is no ground for mixing up the two diseases, and in the second place to indicate the clinical features corresponding to each of the microscopical preparations exhibited

Pityriasis Rubra Pilaris

Pityriasis rubra pilaris is an inflammatory papular disease involving primarily the hair follicle, accompanied by desquamation and presenting the two varieties, the benign and the malignant

The benign variety—In this variety of the disease there is a minute papular eruption, *in size between a pin's* point and head, of a reddish brown colour involving the hair follicles Each papule is pierced by a hair, having a minute scale round the hair, and presenting the appearance of a black point when the hair has been broken off short, but by far the larger number of papules occur quite independently of the hair follicles The skin all over the body becomes very dry, glazed, and tense Great burning is complained of The scaling is best marked on the scalp and forehead and extending down on the back of the neck and the ears is not at all as described by some of a seborrhœic character, being larger than the dry particles of a sicca and not in the least greasy, but of a bright shining character There is a slight feeling of harshness With soothing applications, such as one would apply in an acute erythematous eczema, the whole inflammation subsides, the papules being the last to disappear, the disease ultimately clearing up with a fine desquamation in from three to five weeks Injudicious internal treatment, especially the administration of arsenic, prolongs the disease almost indefinitely In a case which I had under my care some eight years ago I had this fact brought very forcibly home to me After 11 weeks' treatment with Fowler's solution, during which time the patient got steadily worse he was deprived by an accident of his medicine for two weeks when he made marked improvement. Recurrence in this form is very usual, one patient having come to me for three years in succession, being quite free during the intervals. (Any of my former students who remember the case and who may read this article will be interested to learn that last year he escaped altogether.)

The malignant variety.—In the two cases of this form that I have had an opportunity of watching grave constitutional symptoms ushered in both. The appearance of the eruption was preceded by malaise for some weeks; in one case a rigor occurred 48 hours before the onset, the temperature running up to 104° F. The symptoms of the benign variety are intensified, the burning and tightness of the skin being the most distressing symptoms complained of, the conical papules varying in size, and with the inflamed thickened epidermis between they form large patches of a deep red colour, scaling extensively, looking in some parts like exaggerated ichthyotic patches and in others like a dermatitis exfoliativa. Individual papules show a piling up of horny material, sometimes pierced by a hair which is lustreless, twisted, bent, and often broken, the skin being harsh to the touch. The disease lasts a long time, is difficult of treatment, but yields in the end to persistent soothing local treatment and large doses of cod-liver oil internally. I can readily understand these cases corresponding to Hebra's cases of fatal lichen ruber.

CASE 1.—In the case of this patient, a man, aged 48 years, the duration of the present attack had been three weeks. The clinical characters were marked redness of the scalp, forehead, and ears, presenting a glazed appearance, the skin appearing to be tightly stretched; there was fine white desquamation. On the flexor surface of the forearms were a number of minute brownish-red conical papules, some pierced by hairs, others with the hairs broken and presenting minute black points, while the larger number of papules appeared to occur quite apart from hair follicles. Round the hairs there was a continuation upwards of the horny layer, giving the appearance of a fine sheath to hairs. There were thickening and scaling over the backs of the hands and the soles of the feet; there were also some papules seen on the backs of the fingers. The body and lower limbs were free.

Microscopical characters. (Fig. 1, Section 573, removed from the lower third of right forearm.)—There are a hypertrophy of the horny layer over the papule and a slight hypertrophy of the stratum granulosum. Under the papules may be observed a small irregular infiltration not unlike that found in the lichens. These papules are quite independent of hair follicles and correspond to what Unna calls "sinuous papules." In the hair follicles may be seen a hypertrophy of the horny layer, producing a bend in the hair, which is pushed over to the side of the follicle. The lumen of the duct and coil gland is dilated, with swollen epithelium.

Remarks.—The points which I wish to emphasise in connexion with pityriasis rubra pilaris, when taken in conjunction with lichen, are: (1) that although papules occur apart from hair follicles the hair follicles are primarily involved; (2) that in lichen the hair follicles only become secondarily involved and that at a much later stage of the disease; and (3) that there is no tendency to the formation of hyaline material, this alteration being one of the earliest signs of a lichen.

Having thus briefly disposed of pityriasis rubra pilaris, showing, however, I hope, the chief points of distinction between it and a lichen, I will pass on to the more immediate object which I had in view—namely, to show that there is one lichen with four stages, each stage after the acuminate being a direct sequence of the previous one. Not that it is necessary for the disease to go through all these stages, but that each of the stages after the first exhibits a higher type of the disease. The drawings of the microscopical slides will indicate beyond doubt the gradual passing of the early papule to the higher stages, showing a condition of transition which corresponds clinically with the duration of the disease.

LICHEN.

Lichen is an inflammatory cutaneous disease ushered in by an eruption of red conical papules, varying in size from that of a pin's head to that of a split pea, which may develop into flat, irregular, waxy papules, either remaining discrete, becoming confluent, or arranged in rings. These papules may ultimately amalgamate and form lilac-tinted patches, either hypertrophic or, in the severest form, distinctly warty. The stages of the disease are: (1) the acuminate stage; (2) the planus stage; (3) the hypertrophic stage; and (4) the verrucose stage.

The acuminate stage.—In this, the initial stage of a lichen, the papules are of about the size of a pin's head. They are of a bright-red colour with a thin scale on the top, are localised to the wrist and the insides of the knees, or are scattered universally all over the body. Itching is present and is often very intense. The inflammation may subside, the disease ending in desquamation without pigmentation, or, as it more commonly does, it may pass on to the second stage.

The planus stage.—Here the lesions may be limited, as a large quantity of eruption in the early stage does not of necessity mean that many lesions pass on to this stage. However, the typical picture presented is a very extensive universal eruption of conical papules coming out in fresh crops, mixed up with larger, flat, irregular-shaped, dark-reddish papules—which later become waxy, with a tendency to umbilication, more marked according to the age of the papules—the more polished the papule the greater the age and the greater the umbilication. The papules may occur in chains, in definite rings, or in segments. There is often an extensive amount of desquamation of very white scales present. Itching is intolerable and frequently marked redness and infiltration of the skin take place between the papules. The lesions are soft at first, but as they become more waxy they are found to be harder. On the tongue, the palate, and the insides of the cheeks may be seen pin-point red acuminate papules at first, with later white plaques or streaks. The disease may continue for weeks or months in this stage, but more commonly it yields to treatment and subsides, leaving usually only slight pigmentation if it has been untreated by arsenic.

CASE 2.—The patient was a female, aged 43 years, who had been suffering from the attack for 14 days. There was extensive eruption all over the body and the limbs, displaying acuminate papules of the size of a pin's head of a bright-red colour, some of which were "marked" and were seen in the course of from a week to a fortnight to pass on to the second stage and to present flat, irregular-shaped, dark-red papules of a typical character. There were extensive redness and infiltration between the papules, with scaliness. On the inside of the cheeks were red acuminate papules, but no white patches. Itching was severe. The disease ultimately subsided in six weeks, leaving but slight pigmentation present.

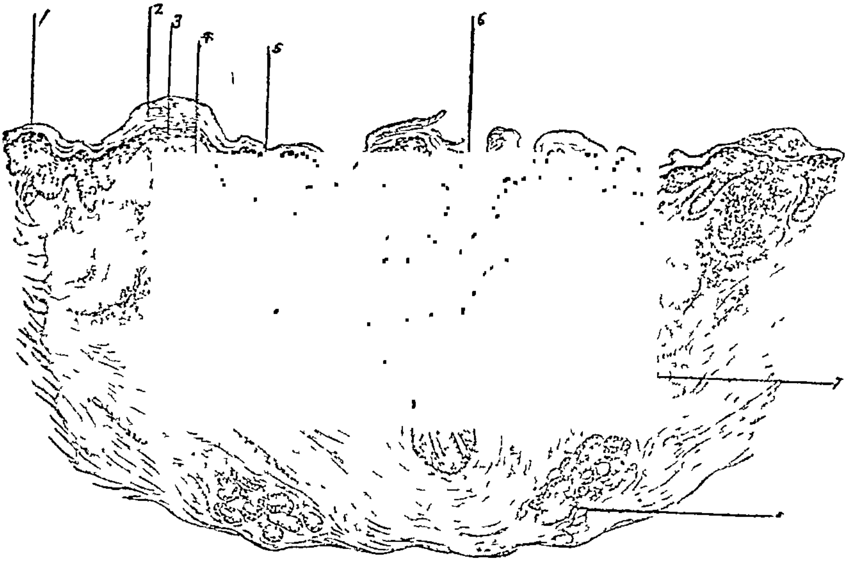
Microscopical characters. (Fig. 2, Section 429, taken from the breast.)—Here may be observed on the extreme left of the drawing (1*a*) an early acuminate papule, with the beginning typical lichen infiltration underneath. On the right (1*b*) is seen the papule as it has developed and passed into the early papule of the planus stage, showing a flatness and enlargement of epithelial cells already becoming hyaline. Here and there may be seen small hyaline pearls. The papillæ are swollen and they form the round characteristic arches, between which is a small irregular infiltration composed of a few mast cells and leucocytes and a number of small pointed cells, the whole being just under the epidermis.

A section (No. 429) (from the same case with a hair follicle beside the planus papule) was taken from the back. It was interesting to observe that the hair follicle was quite normal, the papule having arisen quite apart from it, and although the irregular infiltration was seen round the hair follicle it had maintained its integrity.

In many cases of lichen the general eruption may subside, leaving a few waxy-coloured, flat, irregular papules, itching only moderately, and the patient may not trouble till the itching becomes more intense or the papules more pronounced. Or, again, there may never have been a general eruption, but only a local one which has been followed by these planus papules, and advice is not sought for months or even for years.

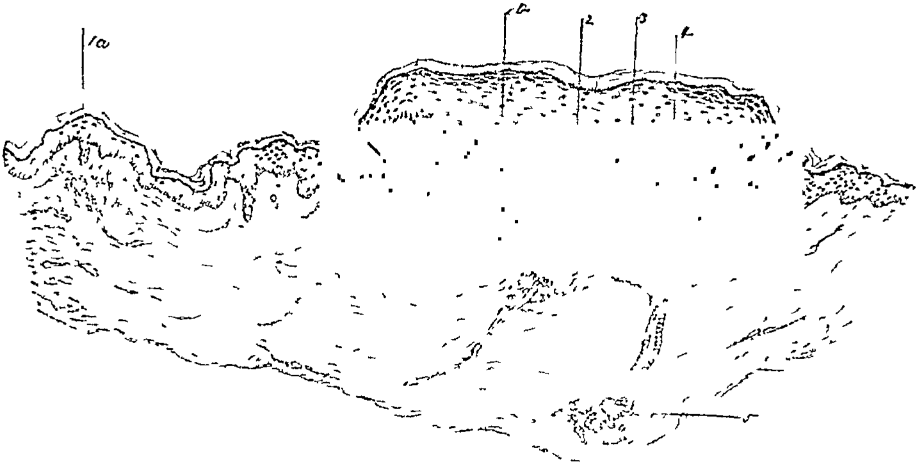
CASE 3.—The patient, a man, aged 48 years, had suffered for two years and he remembered having a small number of red, itching, pointed spots which gradually became flattened and white. There were small groups of papules occurring on the lower third of the flexor surfaces of both forearms. Some of the papules were isolated and large, of a dense consistence, waxy in colour, umbilicated and lined, and others were smaller and occurred in lines of four and five, while there was a beautifully-marked ring on the left wrist. In these papules, in lines and rings, there was a well-marked

FIG 1 (Section 573)



Pityriasis Rubra Pilaris 1 Stratum granulosum 2 Horny layer over papule 3 Flatness of epithelial cells 4 Infiltration situated under papule 5 Sweat duct with lumen slightly wider 6 Hair follicle 7 Infiltration round blood vessels 8 Dilatation of coil gland

FIG 2 (Section 429)



Lichen Acuminatus 1a Early commencement of a lichen indicated by an acuminate papule (lichen acuminatus) with infiltration underneath 1b Further development of 1a going on to show plane papule (lichen planus) 2. Papillæ round and swollen 3 Hyaline pearls 4 In papule enlargement and flatness of epithelial cells which have become hyaline 5 Coil glands with dilated lumen of duct and gland and swollen epithelium lilac tinting, but in the larger there was just the faintest suspicion of it.

A section (No. 560) (waxy papule of planus stage) was taken from the right wrist. In this section could be noticed the increased thickness of the horny layer, which was becoming hyaline. The cells of the stratum granulosum had become hypertrophied and the epithelial cells were larger, flatter, and more hyaline. The hyaline pearls were larger. The sweat ducts were slightly wider than normal. The typical lichen infiltration was composed of small pointed cells, deeply stained, occurring in and round the swollen papillæ body, closely adherent to, and often in lines along, the fine vessels. The endothelial cells of the capillaries were hypertrophied and swollen; some mast cells and leucocytes were scattered about. The connective tissue cells were swollen and increased in number.

Remarks.—These three sections establish (1) the difference between pityriasis rubra pilaris and lichen; (2) the gradual transition of the initial acuminate papule to the full developed flat, umbilicated, irregular, waxy papule of the so-called lichen planus; (3) the fallacy of the evidence that the hair follicles or sweat ducts take any part in the formation of the lichen papules; (4) as a result, that the umbilication is not due or in any way connected with the coil duct; and (5) the important part played by hyaline degeneration, not only in producing its waxy appearance, but also in accounting for the lesions, which were soft at first, becoming harder later.

The hypertrophic stage.—This stage follows as the sequel to the previous ones and seems to be often due to some central irritation, so that it is found following the course of a nerve. Varicose veins in other cases seem to have helped the original trouble to further development, while in quite another class of cases it is impossible to account for the patches sometimes occurring on the forehead and at other times on the wrists except by local irritation from some article of clothing. On inquiring closely it is generally possible to get a history of the initial eruption which has subsided except for the patches complained of, which are made up of the chronic inflammation, not only of the original papules, but of a hyaline degeneration of the tissues between them. These may remain for years, gradually becoming more thickened, often resembling a keloid elevation, varying in colour from a lilac tinting to a deep red, presenting various shapes, sometimes in lines, rings, and irregular plaques, and giving rise in some cases to no discomfort but in others to more or less constant itching. White lines or points may be observed. Scales of a bright white colour are often present, chiefly adhering in the centre. These patches may occur anywhere, but are more frequently seen on the lower limbs.

CASE 4.—In this case the condition had existed for five months. The patient, a man, 54 years of age, remembered distinctly having had about a year previously an itching eruption which lasted for some months. A thickened infiltrated plaque occurred at the junction of the middle and lower thirds of the inside of the left leg, being three inches in width and five inches long. It was very dense, excessively irritable, striated, faintly lilac in colour, and it presented a well-marked irregular outline.

Microscopical characters.—Section 454. Here might be seen hair follicles and sweat ducts dilated and filled out with a hyaline horny layer, hypertrophy of the cells of the stratum granulosum, and an increase in the number of the rows of cells. There were enlarged lymph spaces, owing to the contraction of hyaline epithelium. Well-developed hyaline pearls could be seen and the coil glands with their lumen filled out with hyaline material. There was uniform infiltration extending more deeply into the cutis.

Remarks.—It was interesting to notice (1) that the hair follicles and sweat ducts were now for the first time involved to any extent; (2) the enlargement of the lymph spaces; (3) the gradual enlargement of hyaline pearls; and (4) that pigmentation was more marked.

Verrucose.—This condition has been denied by some and improperly described by others. It is a rare development and certainly, as shown by the microscopical picture, indicates the highest type of lichen.

CASE 5.—In this case the patient was a man, aged 65 years, and the condition had been present for 10 years. There was a dense, hard, infiltrated patch situated over the lumbar region, presenting numerous white lines on its surface, some almost looking like deep cracks, irregular, warty-looking on its surface, quite fixed, itching excessively, at times presenting a lilac tinting all over, sometimes deeper in colour than at other times, but at no time showing any appearance of red.

Microscopical characters (Section 69).—Here everything was in a higher state of development. There were larger cells of stratum granulosum and more rows of them, further widening of hair follicles and sweat ducts, greater development of hyaline degeneration, and larger hyaline pearls. The lymph spaces were more widely dilated and infiltration had extended more deeply into the subcutaneous tissues.

Having thus stated what appears to me to be the true position of lichen I will take some of the points that, according to a recent discussion,[1] seem to vex the dermatological mind.

Nomenclature.—I would draw attention to the statement by the opener of the discussion which I have mentioned that it was at last time to do away with the term "ruber" in dealing with lichen planus. This, I am glad to say, I have systematically done for some years in my teaching, pointing out its uselessness even at the risk of being thought unorthodox, which is the very amusing reason given for its retention by another speaker who says: "I have stuck to it for fear of not being considered orthodox." Surely orthodoxy, though very necessary in the conduct of professional life, for example, tends when imported into science to the cramping of individuality and originality and becomes absurd. The opener of the discussion, however, I regret to say, did not continue in removing useless terms, but having removed the "ruber" on the ground that "the time has come to say to it, as we did to his (Hebra's) revered shade long ago, 'Requiescat in pace,'" he proceeded to create a new name for two cases, one of which he stated was a crimson red eruption of papules *very like* lichen planus, which he calls "lichen planus erythematosus." Then, a little later, he suggested that when the papules were very waxy-looking the term "lichen planus morphœicus" would be suitable. Why this desire to introduce new terms to describe the different shades of colour which may strike the eye of the observer in a disease of many shades and colours? Does it either advance this branch of science or enhance the reputation of the sponsor? Is it not rather an element of weakness, a wasting of time over useless nothings, instead of verifying the diagnosis by microscopical investigation.

Striæ and grey points.—These pathognomonic signs of the French school are useless from a clinical point of view, because they are common to many conditions of inflammation of the skin, being always well marked where there are a thickening and hardening of the horny layer, and not being in any way influenced by the alterations in the cells of the stratum granulosum, but only in lichen dependent on the hyaline condition of the horny layer, which becomes harder in some places than in others, emphasising the normal lines and furrows of the skin just as in psoriasis the waxiness of the horny layer produces the similar condition.

Morbid anatomy.—The last point which I wish to deal with in this discussion is the extraordinary statements made by two of the speakers on the morbid anatomy of lichen. Dr. J. H. McLeod said: "We found that the initial lesion was a cellular infiltration, and that that cellular infiltration was invariably of one type. There were certainly a number of blood-cells present, but the majority of the cells clearly belonged to the connective tissue type. A few of them were of the same class as Unna's plasma cells. The majority of them were typical connective tissue cells." My comment on this is (1) that the swollen connective tissue-cells have nothing to do with the infiltration, they present similar appearances in lichen to those found in other inflammations of the skin; and (2) that the cells of the infiltration are composed of small deeply-stained, somewhat pointed cells, easily distinguished from the connective tissue cells which are much larger than these tiny cells, being tightly fixed to the walls of the capillaries and often in lines. There are no plasma cells, as Dr. McLeod states, but leucocytes in small numbers, a few mast cells, and some pigmentation which becomes increased in the higher types. Dr. James Galloway, while appearing to endorse the statements of Dr. McLeod, went on to say that there were many points of similarity between the infiltration of lichen planus and lupus erythematosus. But this is certainly wrong. Any fairly accurate observer can see that there are no points of similarity either in its appearance, distribution, or in the other cells which accompany it. The whole picture of lupus erythematosus is different, presenting characters as distinct histologically as those which clinically differentiate the two diseases. In neither case ought there to be the slightest difficulty in diagnosing between the two.

---

[1] British Journal of Dermatology, vol. xii., No. 12, December, 1900.

In conclusion, I hope this paper with the microscopical illustrations so well executed by Mr. Max Colhoun may serve to make the very interesting condition known as lichen more intelligible to those who may read it.

Cavendish-square, W.

INFANTILE SCURVY.

BY EDMUND CAUTLEY, M.D. CANTAB.,

PHYSICIAN TO THE BELGRAVE HOSPITAL FOR CHILDREN; ASSISTANT PHYSICIAN TO THE METROPOLITAN HOSPITAL.

IN view of the discussion raised in THE LANCET on the cooking of milk and its effects on nutrition the following cases of infantile scurvy which have recently come under my notice may prove of interest. Cases of this nature are far more common in private than in hospital practice. This is no doubt due to the fact that the same care is not devoted by the mother or nurse to the preparation of the child's food, and that even when fed on patent foods the child often gets in addition "tastes" of unboiled milk and other articles of diet. The children of the lower classes are rarely kept on a diet of sterilised milk or even on patent foods only for any very long time and, as these cases show, the development of scurvy is a very slow process.

CASE 1. *Scurvy due to a prolonged diet of sterilised cream and milk.*—The patient was a female, aged 10 months, living in Surrey. She was brought to me at the age of nine weeks, weighing eight pounds, just as much as when she was born. She had been fed on various kinds of diet. On a diet of cream, milk, water, sugar, and lime water, in suitable quantities and at proper intervals, she gained 73 ounces in 12 weeks and had not a single bad symptom. The food was sterilised for 20 minutes. I did not see her again for five months, during which time she had been fed on exactly the same diet, the same amount and at the same intervals, and the food had been continuously sterilised for 20 minutes. She had now general tenderness of the lower limbs, disinclination to move them, pain on movement, and some swelling of the middle of the right thigh. Two teeth were cut and the surrounding gums were swollen and rather dusky. Four more teeth were almost through. There was no evidence of rickets. The milk mixture was given boiled instead of sterilised, and in addition the child was given barley-water, fruit juice, and a little meat juice. On account of a family susceptibility to tuberculosis, two sisters having died from tuberculous meningitis, and not knowing the source of the milk-supply I did not care to run the risk of putting the child on unboiled milk. Recovery was rapid and uneventful.

CASE 2. *Scurvy due to patent foods.*—The patient was a male, aged 11 months, living at the seaside. For the first three months he was fed on a patent food advertised as suitable for an infant at that age. During the next three months he was fed on another patent food, provided by the same firm, for children at that age. At six months an attempt was made to put him on the third variety of the same firm's preparations, but his digestion was upset, and he was then fed on a malted milk. His first tooth was cut at five months. For three months he had suffered from variable pains, anorexia, and wasting. He was not anæmic. There was a moderate degree of rickets. He had seven teeth. The gums were dusky and spongy. There was general tenderness and pain on movement. On a suitable diet he recovered rapidly.

CASE 3. *Scurvy due to patent foods.*—The patient was a female, aged 11 months, living in the country. Since the age of five months she had been fed on patent foods only and seemed to thrive well, getting very fat. For a month she had been fretful, disinclined to move, and would cry on handling. For three weeks she had been treated for rheumatism. She was very fat, her limbs resembling Bologna sausages. She had seven teeth. The gums were spongy, purplish, and bled freely. The legs were kept partially flexed and she screamed when attempts were made to straighten them. There were general tenderness, pain, and inability to sleep. There was no evidence of rickets. She soon recovered.

CASE 4. *Scurvy due to sterilised milk.*—The patient was a male, aged 15 months, living in a London suburb. He had been fed on milk from a "milk laboratory" since a few months of age. Recently he had been at the seaside and had only returned the day before I saw him. He had 10 teeth, with deep purple congestion of the gums, was very anæmic, sweated freely, cried when moved, and presented general tenderness of the limbs and slight beading. There was marked swelling of the right leg and to a less extent of the right thigh and left leg. This was much the worst case of the series, but the patient recovered very rapidly.

The treatment in each case consisted in a diet of unboiled milk (except in Case 1), fruit juice, meat juice, and barley water. In the fourth case vegetable purées were also given and mashed sieved potato. All these cases occurred in infants of the upper middle class in the social scale and they had all been more or less under medical supervision. Climate does not [illegible] gh it is possible [illegible] copious supply [illegible] of the disease. In all cases the diet consisted of a cooked food, but the disease did not develop for many months. The first case was the mildest, although the food had been continuously sterilised for eight months and it was not necessary to stop cooking the milk in order to cure the disease. The milk was boiled for a few minutes instead of being sterilised for 20 minutes.

It strikes me as a remarkable fact that during the last seven years I have in hospital practice brought up a very large number of infants on boiled milk, with the addition of barley water after the age of two or three months, and yet during the whole of that time no one of them has developed scurvy. Many have had the milk boiled until they have reached the age of one year. The rate of gain in weight has always been satisfactory when the directions have been properly carried out. Consequently I am astonished to read in your valuable journal that a physician of one of the largest London hospitals actually states that numbers of infants "are made peevish, fretful, and even seriously ill by the pernicious effects of boiled milk on their nutrition." In large towns it is absolutely imperative that milk for infants should be boiled, though it is not so necessary that it should be sterilised. In 1895 I examined milk bought in London shops and found that it contained from 3,000,000 to 30,000,000 of micro-organisms in each teaspoonful. Surely no one can urge that such milk is better uncooked than cooked. Under the present methods of milking and distribution of milk it is quite impossible to prevent the contamination of milk and the rapid growth of micro-organisms in such a very nutrient fluid. The only means we can safely devise to minimise the risk is to cook the milk. No chemical treatment of the fluid is proved to be less harmful. It is an established fact that many epidemics have been traced to the milk-supply. Such epidemics are hardly possible from this cause if the milk is boiled, for the common disease germs are readily destroyed by the process. Many maintain that infected milk is a great cause of infantile tuberculosis, and if this is the case it still more strengthens the position of those who insist on the boiling of milk for infants.

Let us consider for a moment the arguments against cooking the milk. In the first place, it is said that it diminishes the nutrient value. Such an argument might be brought forward against many articles of food and yet would not induce us to eat the food uncooked. The experiments of Vassilieff on healthy young men showed that the nitrogenous ingredients and the fats of boiled milk are less readily assimilated than when the milk is unboiled. Koplik's observations on infants showed that the amount of unabsorbed nitrogenous constituents is practically the same whether the milk is boiled, pasteurised, or sterilised, and is greater in each case than when the milk is unboiled. Bendix came to the conclusion that, in the case of infants two years of age, the nutritive value of sterilised and unsterilised milk is practically the same. Weber's experiments on calves showed that the nutritive value of uncooked milk was greater than that of cooked milk. Though there is great liability to error in experimental work which involves very elaborate chemical processes it may fairly be concluded that the nutritive value of milk is somewhat lessened by the process of cooking. Its antiscorbutic properties are also diminished and, in my opinion, the longer the subjection of milk to a high temperature the greater the diminution in these latter properties. For this reason the proprietary foods made from milk are more likely to lead to scurvy than is a diet of boiled milk.

There is no doubt that sterilised milk as a continuous diet will in time produce scurvy. It is equally clear that such a diet must be continued for many months—eight months in Case 1 and then only a very mild form of the disease; more than a year in Case 4 and hence a more serious attack. In both these instances nothing else was given. But are we to condemn the cooking of milk for such a reason as this? I can point to a very large number of infants who have been fed on boiled milk for many months and have never developed scurvy and have gained weight as rapidly as the most anxious mother could wish. The other two cases illustrate still more strongly the disadvantages of cooked foods, especially the prolonged cooking to which the proprietary foods are subjected in order to preserve them. Even in these instances the scurvy took many months to develop and a little modification of the diet would have prevented it entirely.

In conclusion, I most strongly maintain that the boiling of milk for infants is essential, save under most exceptional surroundings; that the longer milk is cooked and the higher the temperature to which it is submitted the less will be its nutritive and antiscorbutic value; that such deterioration in its properties is of no serious importance, if it is not forgotten, for it can be very easily remedied; that any healthy infant can be brought up on a diet of boiled cow's milk, suitably diluted and mixed and given in proper quantities at due intervals; that failure to bring up infants on such a diet is rarely, if ever, due to the fact that the milk is cooked, but is due to some error in the mode of feeding or the amount given; that the very slight tendency to scurvy can be easily remedied by the addition of barley-water and a little fruit juice; and, finally, that healthy boys at a public school can drink uncooked milk with impunity as long as it is not contaminated with disease germs, but that to base on such a fact an argument that infants should be fed on unboiled milk is merely a delightful instance of illogical reasoning.

Upper Brook-street, W.

ON X RAYS IN THE TREATMENT OF LUPUS AND RODENT ULCER.

BY JAMES STARTIN, M.R.C.S. ENG.,

SENIOR SURGEON TO THE LONDON SKIN HOSPITAL.

IN September, 1899, I found the beneficial effects of the x rays in lupus, rodent ulcer, and certain other affections of the skin. I have been working with an instrument provided by Mr. Isenthal, consisting of a 15-inch sectional coil worked at 16 volts with a mercuric interrupter. The average speed of interruptions is about 250 a minute, the average current about from three to five ampères. I used at first a five-inch tube, then a smaller one made by Cox. I place the tube generally at a distance of five inches between the anti-cathode and the part to be exposed, and the duration of the exposure lasts from 10 to 15 minutes, giving four or five exposures on consecutive days. In cases of lupus the skin becomes slightly red after the first four exposures, the nodules bright and shining, and the pus dries up, with no doubt destruction of the bacteria. After a few days scabs form, then drop off, leaving a red glazed surface, which may or may not scab over again. This process goes on *until* no more scabs are formed and the surface is smooth and normal. The surfaces acted upon become slightly œdematous and a healthy epidermis begins to form. A good deal of reaction takes place in the diseased areas, such as we used to see on the administration of tuberculin a few years ago, but without any detrimental constitutional effects. This is followed by a copious discharge of serous matter which ceases in a few days.

Whether the x rays operate injuriously on the micro-organisms or whether phagocytosis becomes more pronounced under the slight stimulus has not yet been definitely made out. What, then, is this curative action so destructive to bacteria and what is the agent that produces it? In what manner do the ethereal vibrations of the x rays correspond to the ultra-violet, photo-chemical rays of the solar spectrum?

As far as my experience leads me at present the most suitable cases for treatment by the x rays are lupus, both true and erythematous, rodent ulcer, epithelioma, psoriasis, localised eczema, lichen, alopecia areata parasitica, and other parasitic diseases of the ringworm class. To these may be added superficial cancerous affections and dermal tuberculosis. When we can get the penetrative power to extend still further, if it be true that cultivated bacteria can be destroyed in from 15 to 20 minutes, the x rays show a future use in antiseptic surgery.

CASE 1.—The first case I wish to record is that of a man, aged about 60 years, who came under my notice in September, 1898, with a large rodent ulcer extending over the whole frontal region down to the supra-orbital and nasal region, with deep ulcerations, some extending to the periosteum, and having the distinct crateriform edge characteristic of rodent ulcer. I used various treatments by caustics, ethylate of sodium, chromic acid, salicylic collodium, powders and ointments with varied success. Nevertheless, the disease steadily advanced, so that in June, 1900, I decided to put him under the x-rays treatment and gave him his first exposure on the 18th of that month, repeating the exposure for seven consecutive days, for 15 minutes at six inches from the skin. After the first four exposures much disturbance of tissue was noticed. The skin became red and glazed, the edges red and inflamed, and a copious discharge took place. After a day or so all discharge ceased and the sore began to take on a more healthy appearance, granulation tissue beginning to form. He went home with a simple iodoform dressing and I saw him again in July. The appearance of the wound was more healthy, but still there were two large excavated ulcers of about the size of a two-shilling piece in the centre of the area. I decided to give him a few more exposures, seven, and again in October, with the result that the raised edges of the wound became flattened, granulation tissue and an apparently healthy skin forming on most of the old sites of disease.

CASE 2.—The patient was a strong man who came under my notice three years ago with a deep foul ulcer on the forehead, nose, and face near the inner angles of both eyes, covered with thick crusts and very tender and sore, caused by a wound which he had received from the branch of a tree. I put him under various treatments by caustics, ethylate of sodium and salicylic and iodoform dressings, as in the other case, with varied results, and on Oct. 22nd last I sent him into the hospital in Fitzroy-square and gave him 10 exposures to the x rays with very beneficial results. The ulcers on the forehead and nose have nearly healed and only the ulceration in the corner of the nose and right eye remains. It is difficult to direct the rays there on account of the near proximity of the eye. The sight is unaffected at present.

In both these cases there was some considerable dermatitis, which was to be expected, and we need not be afraid of it as it promotes that disintegrative resolution in the tissues which must be present in the formation of a healthy cicatrisation. The surrounding skin has also taken on a more healthy appearance. The scars that remain are more natural and resemble the surrounding skin.

CASE 3.—A girl, aged 17 years, came under my care at the hospital in May, 1890. It was one of the worst cases of true lupus that I have seen for some years, with perforation of the bridge of the nose. I commenced treating her with tonics, quinine, and arsenic and using an antiseptic dressing of salicylic acid, iodoform, and vaseline, and on June 20th I gave her seven exposures with much the same result as in the two previous cases. There was considerable disturbance in the ulcers with much discharge for a few days. Then there followed a complete drying up of the sores and the assumption of a much more healthy appearance.

CASE 4.—A young married woman, aged about 30 years, had well-marked butterfly lupus erythematosus on both cheeks and on the bridge of the nose. The patches, which were crimson red and inflamed, were of about the size of a two-shilling piece. This patient came under my care in October, 1897. I put her under treatment of various applications, salicylic collodion, &c., with some good results, but the case proved to be tedious, so I determined to put her under the x rays at intervals of three days for a few weeks on Nov. 5th last. She has now had six applications with capital results. Cicatrisation has taken place.

CASE 5.—This patient, a young woman, aged about 21 years, came under my care at the hospital in March, 1900, with psoriasis of the legs, the arms, and the body. After treatment with tonics, arsenic, and tarry preparations she got fairly well excepting one obstinate patch about six inches long by three inches broad on the leg. I exposed her to the x rays for seven exposures at intervals of about three days, with the result that in about a fortnight from the last exposure the whole patch completely vanished, leaving a healthy skin.

In the face of such facts it must be considered that we have in the x rays a valuable therapeutic agent.

Harley-street, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF COCAINE POISONING.

BY KENNETH FRASER, M.B., CH.B. ABERD.,

JUNIOR HOUSE SURGEON, ROYAL ALBERT EDWARD INFIRMARY, WIGAN.

A WOMAN, aged 59 years, was admitted on March 11th, 1901, to the Royal Albert Edward Infirmary, Wigan, suffering from rodent ulcer situated above, and to the outer side of, the right orbit. She had been operated on about a year previously, when a portion of the frontal bone had been trephined. On the present occasion she was considered to be beyond operative treatment. On the 21st formalin (40 per cent.) was applied to the surface of the ulcer, causing great pain. On the 23rd, previously to the application of the formalin, the affected part was sprayed with 10 per cent. of cocaine. She was sprayed twice a day. On the evening of the 25th the patient became quiet, spoke in a dazed manner, and answered questions after some hesitation; she then became irritable, lying with her head buried in the pillow, and soon drifted into unconsciousness. The pulse was rapid, full, and of high pressure. The respirations became laboured, irregular, and of the Cheyne-Stokes character. Convulsive clonic spasms passed over the whole of the body, beginning with the muscles of the mouth. Then the patient broke out into a cold perspiration and saliva ran freely from her mouth. The face was pale. The pupils were normal in size and reacted to light. There was no change in the temperature. On artificial respiration being tried the arms could not be raised above the level of the shoulders. Brandy was administered and five minims of nitrite of amyl were given and also inhalations of oxygen. Boric fomentations were applied to the affected part half-hourly. In the course of three hours the patient regained consciousness and dropped into a peaceful slumber The following morning she felt quite well but did not remember anything of the previous night. She had received in all about five grains of cocaine. I am indebted to Mr. Berry, under whose care the case was admitted, for permission to publish these notes.

MALIGNANT DISEASE OF THE TESTICLE IN AN INFANT.

BY H. J. CLARK, M.R.C.S. ENG., L.R.C.P. LOND.

THE following exceptionally rare case of malignant disease of the testicle in early infant life is worthy of record.

The second child of exceptionally healthy parents was born in January, 1899. At birth the testicles had descended and no abnormal condition was observed until the child was 10 weeks old, when a slight enlargement of the left testicle was observed, without, however, any apparent cause. The enlargement in the gland increased gradually until the child was 11 months old, when it had attained to the size of a small hen's egg. There was an entire absence of swelling in the inguinal or neighbouring glands. On removal the testicle weighed 29 grammes After operation the child did well and at present looks healthy and free from any neighbouring glandular implication.

Swanage.

MEASLES AT DARTMOUTH.—At the meeting of the Dartmouth Town Council held on July 9th Mr. J. H. Harris, the medical officer of health, reported that during the recent epidemic of measles 672 cases of that disease were notified. Mr. Harris added that there was an outbreak of measles in 1895, when 672 cases were also notified.

MILL ROAD INFIRMARY, LIVERPOOL.

A CASE OF CÆSAREAN SECTION FOR MALIGNANT DISEASE OF THE UTERUS; RECOVERY OF MOTHER AND CHILD.

(Under the care of Dr. NATHAN RAW.)

WHEN the cervix of a pregnant uterus is discovered to be extensively affected with malignant disease and the pregnancy has reached the seventh month there can hardly be any question that the most suitable treatment is a Cæsarean section followed by complete removal of the uterus, should that be possible. The mortality at the present day from Cæsarean section is low in cases in which it is performed before the onset of labour; but if the operation is not undertaken until labour has lasted for many hours the consequent exhaustion must necessarily exert a very harmful influence on the prognosis.

A woman, aged 30 years, was admitted into the Mill-road Infirmary, Liverpool, on May 10th, 1901, suffering from anæmia and pregnancy at the seventh month. Her father died from cancer of the stomach and her mother died from cancer of the breast She had had seven children, of whom three were alive and well; the others died in infancy. During the last four months she had had repeated and constant hæmorrhages from the vagina, together with an offensive discharge. On admission she was pale, extremely anæmic, and very weak. The pulse was 100, small, and thready. She had lost flesh rapidly and suffered constantly from headache. On examination per vaginam there was extensive cancer of the cervix of a fungoid nature, evidently of rapid growth; it bled very readily and was pretty firmly bound down and fixed in the right fornix. The uterus was not very moveable and on examination through the speculum the cervix had a cauliflower appearance. She was evidently going rapidly downhill, as the bleeding recurred two or three times every day. The whole circumstances were explained to her husband and herself and they both agreed to the proposition of Cæsarean section

[illegible] nder ether. Dr. Raw made [illegible] the thin abdominal wall. [illegible] to the middle line and the [illegible] large cotton sponges. The uterus was then opened by a long incision extending from the fundus to the lower segment. Unfortunately the placenta was attached right opposite the incision and Dr. Raw had rapidly to cut through it and to separate it from the uterine wall. It bled pretty freely, but the hæmorrhage was soon controlled The membranes were then hastily opened and the child was extracted by a leg and handed to an assistant. It made no effort to breathe for at least seven or eight minutes although the heart was beating well. Finally it responded to stimulation and was soon all right. On examination of the cancerous growth from within the abdomen it was found to be too extensive to remove completely, and as the patient was very collapsed it was decided to proceed no further The uterus was carefully sutured by 10 deep silk sutures and several superficial ones. No drain was passed through the cervix for fear of infecting the uterus from the malignant growth. The abdomen was closed without any drainage and the patient was put back to bed. She was profoundly collapsed and had to have several pints of normal saline solution per rectum as well as hypodermic injections of strychnine She soon recovered, however, the abdominal wound healed by first intention, and she made a steady recovery and convalescence.

The child was nursed by a foster-mother for a week and was then fed in the ordinary way. The mother is gaining in weight, the hæmorrhage has ceased as well as the offensive discharge, but, of course, the malignant growth is still present. She is, however, comfortable and free from pain, and the child is progressing favourably.

Remarks by Dr. RAW.—Cancer of the uterus is a terrible affliction at any time, but when complicated by pregnancy as far advanced as the seventh or eighth month it behoves the medical attendant to adopt some heroic line of treatment if he is to preserve the lives of both mother and child. It is a well-known fact in obstetric practice that cancer when once established in the cervix progresses at a much more rapid rate during pregnancy than when unimpregnated, and that the bleeding from the cancerous growth is profuse and continuous, especially during the later months of pregnancy; in fact, so excessive may it be as to endanger the life of the patient from progressive anæmia. To allow the pregnancy to go to full term would be to subject the mother to serious risk of her life either from severe hæmorrhage or rupture of the uterus, in addition to which the child would in all probability die either before or during the tedious labour. To attempt to deliver a living child through the cancerous mass either by turning or forceps would, I think, be futile, whilst even to perform embryotomy would set up increased hæmorrhage during the operation, which the obstetrician would have little chance of controlling. The medical attendant has to consider what is best for both mother and child, and there can be no doubt that Cæsarean section with, if possible, complete removal of the cancerous uterus is the correct and scientific treatment.

Sir James Simpson in referring to the operation of Cæsarean section said in 1871: "Accoucheurs sometimes—but fortunately very, very rarely—try to save the infant's life by having recourse to this operation [referring to Cæsarean section], an operation by which, however, the mother's life is almost inevitably sacrificed." What progress surgery has made during the 30 years since that opinion was written. A surgeon would now undertake the operation of Cæsarean section under proper conditions with a confidence that it would be successful, and there can be no doubt that very many lives, both maternal and infant, have been saved by this means. Of course, if the patient comes under our notice in the very early months of pregnancy the proper course to adopt would be to induce premature labour, but in this case the patient was first seen at the seventh month.

Dr. W. J. Sinclair states that "in advanced cases of cancer of the uterus when the disease is discovered at or about full term any treatment is unsatisfactory. Cæsarean section by any of the methods gave disappointing results. In eight cases quoted of ordinary Cæsarean section all the mothers died, whilst after Sänger's Cæsarean section of 13 women only three survived for a month or six weeks; most died directly after the operation." In the face of these terrible statistics it is satisfactory to note that this woman was saved as well as her child. It would have been an additional satisfaction to have removed the cancer, but this was impossible—in fact, any attempt to have done so would have been disastrous to the patient as the disease was too far advanced.

I have to express my great thanks to Dr. T. B. Grimsdale for his kind assistance and also to my colleagues for their great care in the treatment of the case.

LEEDS GENERAL INFIRMARY.

A CASE OF A PERITONEAL "BAND" INTERFERING WITH PERISTALSIS OF THE CÆCUM.

(Under the care of Mr. W. H. BROWN.)

IT is only of recent years that the importance of peritoneal adhesions has been appreciated. Many obscure and indefinite pains in the abdomen have been found to be due to peritoneal bands which have not caused any marked intestinal obstruction but have interfered with the peristaltic movements of some portion of the bowel It is not improbable that many cases of intractable dyspepsia are due to similar adhesions of the stomach

A man, aged 58 years, had been quite well up to last Christmas, but since that time he had been subject to a gradually increasing discomfort in the right iliac fossa. In the past six weeks a swelling had appeared at times, causing much pain when present. On admission he appeared to be fairly well On palpating the right iliac region a swelling could be provoked, in size resembling a clenched fist; at first this was very hard, but it then slowly softened and disappeared. When the swelling was at its height the patient suffered great distress. It seemed likely that something, probably a band, was interfering with the movements of the cæcum. The abdomen was opened over the cæcum and a band was seen about half an inch wide and three inches in length, anchoring the bowel to the abdominal wall just above Poupart's ligament. This was ligatured and divided. The patient made an uneventful recovery.

Remarks by Mr. BROWN.—The case related is interesting from the fact that there had been no previous inflammatory attack to account for the presence of the condition found at the operation. Without any signs of actual obstruction the band caused symptoms which suggested a gradual obstruction being in course of formation. The effect of the existence of similar bands partially preventing normal peristalsis may account for the story one hears at times that patients feel something "give way inside them" after which their former "colic" pains disappear. The cæcum in the present instance behaved much in the way that a horse does when restrained too suddenly—i.e., rearing; the peristaltic wave being checked the contracting bowel rose up and became perceptible through the abdominal walls.

Medical Societies.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

Demonstration of Clinical Cases.—Fœtal Rickets.—The Treatment of Endocarditis.—Tuberculosis of the Choroid.—Syphilis transmitted to the Third Generation.—Meningitis treated by Drainage.—Pneumococcal Peritonitis.

THE provincial meeting of this society was held on June 29th at the Medical Institution, Liverpool, Mr. ROBERT JONES being in the chair.

Clinical cases were demonstrated by the CHAIRMAN, Dr. J. R. LOGAN, Mr. K. W. MONSARRAT, Dr. C. J. MACALISTER, Dr. LLOYD ROBERTS, Mr. W. THELWALL THOMAS, Dr. JAMES BARR, Dr. STOPFORD TAYLOR, Dr. NATHAN RAW, and Mr. G. P. NEWBOLT.

Dr. HENRY ASHBY (Manchester) related a case of so-called Fœtal Rickets. The mother was 46 years of age and the infant was her fourteenth child, born at term and well nourished. When seen at two weeks there were cranio-tabes, deformed chest walls, and five fractures, including both humeri, the left radius, the right ulna, and the left femur. Three weeks later the right femur fractured. The infant eventually made a complete recovery. Dr. Ashby doubted if such cases were examples of true rickets, but they rather resembled, he thought, the osteoporosis produced by feeding puppies on food deficient in salts of lime.

Dr. RICHARD CATON (Liverpool) read a paper on the Treatment of Endocarditis based upon about 500 cases of that disease occurring in acute rheumatism and chorea. He advocated (1) absolute rest in bed for several weeks; (2) the application of a series of small blisters in the region of the first four dorsal nerves in front, followed by poulticing; and (3) the internal administration of sodium iodide. To be of service this treatment must be commenced in the first fortnight or so.—Dr. WILLIAM CARTER bore testimony to the great utility of the method.—Dr. A. ERNEST SANSOM thought blisters a little less than worthless in endocarditis.—Dr. MACALISTER advocated blistering and rest both in endocarditis and in pericarditis. Instead of a blister an ointment of the red iodide of mercury (1 in 8) might be employed.—Dr. BARR spoke of the good effects obtained from blisters in the treatment of acute rheumatism.—Dr. H. R. HUTTON testified to the rapid disappearance of pericarditis under blistering.—Dr. CATON, in reply, said that in acute rheumatism he used the salicylates along with small blisters to the joints.

Dr. GEORGE CARPENTER and Mr. SYDNEY STEPHENSON communicated a paper upon Tuberculosis of the Choroid, which will be found at p. 134 of our present issue. The communication was illustrated by microscopical preparations and by numerous paintings of diseased eyes.—Dr. SANSOM and Dr. ASHBY discussed the paper.—Dr. WARRINGTON asked whether tubercles in the choroid were observed except in the last stage of illness.—Dr. CARPENTER, in reply, said that in the acute cases mentioned in the paper tubercles were found in the choroid from one day to six weeks before death. Tubercle in the choroid did not necessarily warrant a grave prognosis, since some of the cases became obsolescent.

Dr. D. M. **HUTTON** (Southport) read a note on a case of Syphilis transmitted to the Third Generation. The grandfather produced a certificate before his marriage certifying that having had syphilis he was cured. The mother suffered from specific psoriasis. The child died from congenital syphilis at the age of five weeks.—Dr. **ASHBY** thought that the child might have succumbed, not to syphilis, but to a pseudo-syphilitic process of septic origin.—Dr. **EDMUND CAUTLEY** inquired whether there was any post-mortem evidence of syphilis in the infant.—Dr. **GEORGE A. SUTHERLAND** could not accept the psoriasis present in the mother as pathognomonic of syphilis.—Dr. **HUTTON**, in reply, said that the whole question resolved itself into one of possibilities and probabilities. Transmission in this case could not be demonstrated, but it was highly probable.

Mr. **MONSARRAT** (Liverpool) read a note on two cases of Meningitis treated Surgically by Drainage. The results were fairly satisfactory. The choice of a route for drainage was discussed.—Dr **CAUTLEY** dwelt upon the initial difficulty of distinguishing between simple basic and tuberculous meningitis. In his own cases the result of surgical interference had been uniformly unfavourable.—Dr. **LOGAN** mentioned a case of chronic hydrocephalus where the lateral ventricle had been drained, but the child died some months later.—Mr. **DAMER HARRISSON** had passed chromicised gut into the lateral ventricles for the purpose of draining fluid into the base, but he was not inclined to proceed with the operation —Mr. **MONSARRAT**, in reply, thought no operation satisfactory that did not combine ventricular drainage with drainage of the subarachnoid space.

Dr. **JOHN H. BRYANT** read notes of a case of Pneumococcal Peritonitis which he had observed in a girl, aged four and a half years. The abdomen was opened, general acute peritonitis was found, and pneumococci were demonstrated in the effusion. At the necropsy there was no pneumonia or pericarditis, but pleurisy and peritonitis were present. Dr. Bryant was inclined to think that so-called idiopathic peritonitis was of pneumococcal origin.—Dr. **JAMES BARR** discussed general infection with the pneumococcus as shown by pneumonia, pleurisy, peritonitis, and meningitis.

The following communications were taken as read :—

Mr. **R. CLEMENT LUCAS**: Removal of a Nail from the Second Portion of the Duodenum.

Dr. **JOHN MCCAW** (Belfast): Notes of a case of Infantile Scurvy.

Dr. **MACALISTER** (Liverpool): Observations on Cirrhosis of the Liver and Endocarditis in Children.

Dr. **JAMES CARMICHAEL**: Bimanual Examination in the Diagnosis of Abdominal Disease in Children.

Reviews and Notices of Books.

A Civilian War Hospital: being an Account of the Work of the Portland Hospital and of Experience of Wounds and Sickness in South Africa, 1900, with a Description of the Equipment, Cost, and Management of a Civilian Hospital in Time of War. By the Professional Staff—**ANTHONY A BOWLBY**, C.M.G., F R C.S. Eng., Senior Surgeon; **HOWARD H. TOOTH**, C M.G., M.D. Cantab., F.R.C.P Lond.; **CUTHBERT WALLACE**, M.B., B S. Lond., F.R.C.S Eng.; **JOHN E. CALVERLEY**, M.B., B S, M.R.C.S Eng.; and Surgeon-Major **KILKELLY**, C.M.G., Grenadier Guards, Principal Medical Officer in Military Charge. With numerous Illustrations London: John Murray. 1901. Pp. 343. Price 12s.

THE reader of this book will, we think, rise from its perusal with the feeling that it is what it pretends to be and that it fulfils the description given on its title-page. It is a record of the fitting out and organisation of a civilian war hospital and of the work that it did in the field. Apart altogether from the scientific value (which is considerable) of the contributions by the professional staff to the more strictly medical and surgical aspects of the war it is an instructive and useful book, for it contains much carefully considered and well-arranged information with regard to a number of practical points which is likely to prove serviceable in the organisation, fitting out, and equipment of civilian war hospitals on the occasion of future expeditions of a similar character. And we may here say, *en passant*, that future wars when conducted on anything like a large scale will inevitably, as we believe, give rise to increased calls upon the civil profession of this empire. However good and bountiful Government provisions for war may be they cannot be made and maintained upon such a scale and in such variety in point of *personnel* and *matériel* as to cope with all the requirements. The cost alone of a permanent establishment would be prohibitive and in any case the provision would inevitably have to be largely supplemented by voluntary and philanthropic aid. To this end, we may parenthetically remark, we have advocated that as far as the *personnel* is concerned, a list should be kept and maintained by the Government of the members of the junior medical and surgical staffs of the large civil hospitals of this country and its colonies to whom recourse could be had for professional aid in time of need. If we have not already reached, we are nevertheless approaching, the time when Nelson's famous signal will have to be, not what England, but what the British Empire, expects as the duty of its subjects. When this time comes and is realised books of this kind will be largely consulted.

But to turn now to our more immediate purpose—namely, the consideration of the volume itself—we may say that on referring to its pages in order to see the number of subjects and passages which we had marked for notice or reference it becomes at once apparent that in order to review the work as it deserves to be reviewed a far larger amount of space than we can give to it would be demanded and even then much would be left unsaid. We hope, therefore, that our readers will peruse it for themselves.

We are glad to notice that it is gracefully dedicated to Surgeon-General Wilson, K.C.M.G., the principal medical officer of the army in South Africa and to the officers of the Royal Army Medical Corps and the civilian surgeons of No. 3 General Hospital. This serves to indicate the professional harmony and good fellowship which existed between the civil and military medical elements. The "Portland" was the first of the civilian hospitals to be equipped and sent to South Africa and was probably also the first voluntary hospital attached to the British army at the front.

Surgeon-Major Kilkelly, Grenadier Guards, and principal medical officer of the hospital, deals with the *personnel*, equipment, and interior economy, and in the course of 17 pages—after briefly alluding to the transport difficulty in war and the necessity for bearing in mind in fitting out war hospitals that the lighter the hospital the quicker and the more completely will it reach its destination, and after adverting to the evacuation system and principle which is followed and the machinery employed—manages to embody a number of useful and practical points in the course of his observations

Mr. Bowlby, the senior surgeon, follows with a brief description of the career and work of the hospital. Rondebosch, five miles from Cape Town, was the place fixed upon by the military authorities for it to commence its operations. This was a fortunate position in several respects, for it was in proximity to the three large base hospitals already established and in close companionship with No. 3 General Hospital at Rondebosch. Altogether the medical staff of the Portland Hospital had some 1000 beds available where they could see the sick and wounded, who had been sent down after the battles of Modder River and Magersfontein. They had thus an unrivalled opportunity of acquiring a large experience of gunshot wounds, and subsequently, when the epidemic of enteric fever began to be serious in the camp at Modder River station, of that disease. Orders were afterwards received for the hospital to proceed to Bloemfontein which was reached on April 14th after having been preceded by an advanced party to choose a camping ground and to make the necessary preparations. The hospital took the whole of its possessions with it and it was well that it did so, for it was almost impossible to get anything sent up to Bloemfontein for weeks afterwards. During its stay at Rondebosch of just three months the hospital had had altogether 477 patients. Everything went uncommonly well with the medical service and its hospitals during the earlier and very trying stages and events of the war; but at Bloemfontein, as we all know, things were very different owing, as we have contended, to conditions and circumstances which were beyond the power of the medical service to have foreseen and prevented. The general health of our troops at Bloemfontein was, mainly from disease causes, very bad. Enteric fever, diarrhœa, dysentery, &c., were prevalent and, after the nature of such camp diseases, went on increasing at a rapid pace and in a more than geometrical ratio. Many of the camps had become contaminated and the health of the troops immediately improved when the general in command, at the instigation of the principal medical officer, changed the site of the camping ground. The very great importance of this as a sanitary measure is a matter on which we have fully commented in the various articles which have appeared in THE LANCET about this and other campaigns and it is one which is not sufficiently accentuated in our text-books. The invariable rule should be in the event of any outbreak of infectious disease in camp to change the site and, indeed, under ordinary conditions of campaigning to do this periodically as a measure of prophylactic hygiene. With the month of July came a remarkable change—empty beds and empty tents; the whole of the sickness and overcrowding had come and gone, we are told, in three short months and the work of the Portland Hospital in South Africa soon afterwards came to an end. During its stay from December to July this work is summarised as follows. The hospital admitted 1009 officers and men, and of these 37 died, 159 returned to duty, 303 were discharged to convalescent camps or hospitals, 98 went to England, and 412 were transferred to other hospitals at the base. It may be mentioned that of 303 surgical cases only three patients died.

Chapter III., embodying notes on the equipment and *personnel* of civilian war hospitals, gives some very useful and practical details. We are all in favour of simplicity and practicability of detail generally, and especially with regard to medical and surgical equipment and appliances—matters which have not, we are glad to say, been lost sight of in this book. We observe that it is considered absolutely necessary that all hospitals at the seat of war should have one Royal Army Medical Corps officer in charge. An account of the various marquees and tents used for hospital purposes is given, with a comparison of their respective merits and demerits one with another, together with a record of results, with which, speaking generally, we agree, as we do with the remarks on the unnecessary weight and size—width especially—of the regulation iron bedsteads in use at military hospitals, as well as with those on medical and surgical stores, antiseptic dressin,gs x-rays equipment, medical comforts, &c. We may interpolate a remark here that some carpenters and artificers would form a useful addition to the hospital staff (field and base). as was done in the Afghan campaign of 1878-79-80. This brings us to ambulance wagons. We quite concur in the assertion that a perfect ambulance wagon for field service has yet to be devised. That of the army regulation pattern is strong but it is too heavy and cumbersome, and, like so many things which are the outcome of committees, it is designed to provide for, and to accomplish, too many objects. Those of American pattern are light and fairly good. The Indian tonga is stated, as the result of experience, to have been the best conveyance for the wounded in South Africa. Those of our readers who have been in India and who have journeyed by tonga to the hills will realise that these vehicles are very good of their kind, but the range of their usefulness in warfare is, we imagine, nevertheless a limited one, and a really good ambulance wagon for the sole purpose of carrying the wounded has yet to be constructed. Wherever available, the easiest, safest, and best transport for wounded is by water in towed flat-bottomed barges and for land transport by Indian dhoolie-bearers. As to vehicular wheeled transport, we have not yet, as we have said, discovered a method suitable for general purposes.

We come next to the section devoted to a description of the medical work of the campaign by Dr. H. H. Tooth, assisted by Dr. J. E. G. Calverley, which strikes us as affording an able, clear, and eminently readable account of the subject. The most important place is naturally given to enteric fever, without which the medical casualties of the campaign would have been relatively insignificant. After all that has been written and said upon this subject it is refreshing to read the impressions derived from a carefully considered inquiry into the facts—these being stated in a scientific and judicial spirit. The subject has been already so fully dealt with in our pages that there is no need again to discuss it now. It must suffice to state generally that we concur in the causes assigned for, and the medical history given of, the origin, dissemination, and course of the epidemic. The views of the writers in these respects are very similar in effect to those which we have put forward. Touching the possible part played by flies we may notice an interesting point which might be made the subject of future investigation. Cultivations were made at the laboratory of St. Bartholomew's Hospital from the excreta of flies voided on temperature charts which had been kept in the enteric fever tents but with a negative result as far as the isolation of the bacillus was concerned. The failure to demonstrate the typhoid bacillus is not surprising considering that more than three months had elapsed and that the bacilli might have been destroyed in the alimentary canal of the insect. The organisms might, however, as suggested, be carried about on the legs and bodies of the insects. The recent investigations of Dr. Horton-Smith recorded in his Goulstonian Lectures, 1900, in regard to the fæces not being by any means the only channel by which the bacilli are removed from the body, and to the very important part played by the urine in this respect, are very pertinently referred to in connexion with the extreme difficulty (to say nothing of the influence of other conditions) of preventing the spread of infection under the conditions of war. That the bacilli may live and appear in the urine for a long time is undoubted. These investigations are very significant and serve to show, at any rate, how futile it is, as is too often done, to draw conclusions from imperfect data.

The prevalence of diarrhœa or looseness of the bowels is so common among troops otherwise strong and healthy on service in hot climates that it may almost be regarded as physiological, but it soon oversteps its limits, and its relations to enteric fever and dysentery must never be lost sight of. As regards the statistics relating to enteric fever we may congratulate the medical staff on the successful results—a percentage of deaths amounting to 12·5 only. The figures showing the results of inoculation, although favourable to the practice, are still too small for drawing any accurate conclusion. If we do not enter upon the clinical remarks and description of cases of this and other fevers, dysentery, diarrhœa, and other diseases incidental to field service, it is not because we do not regard the writer's observations as valuable, for they distinctly are so, but because but little space remains to us for the consideration of the interesting and instructive section contributed by Mr. Bowlby and Mr. Wallace on the surgical work of the war.

In this section a succinct but sufficiently clear and detailed description is given of the weapons and projectiles used in modern warfare; the surgical aspects of modern rifle fire are considered, as are the results of the alteration from the old to the new rifle as affecting the surgical side of the question. The several points are separately taken up and discriminately weighed. When the small size of the Mauser bullet, its extreme range, and its comparative novelty in warfare are considered it is not surprising that some differences of opinion as to its effects should exist. Speaking generally there can be no doubt that both civilian and army surgeons were much impressed by the favourable course that the wounds, as a rule, ran; it was one of the most striking facts of the war. At one time it seems, say the writers, that almost any part of the body can be perforated with impunity, and the observer is inclined to agree with those who regard the Mauser as a humane bullet, while at another time and almost before that impression has passed away another case occurs which gives rise to the opposite opinion. Some striking instances are cited in illustration of this. The general trend of the authors' observations and experience is, on the whole, to modify the somewhat optimistic conclusions that have been expressed. One thing, however, appears clear—that to those who had the opportunity of comparing and contrasting the results of their experience in South Africa with those of previous wars the difference seemed marvellous, and a great change, amounting almost to a revolution, has taken place in the surgical treatment of gunshot wounds. With regard to wounds of the abdomen, while recognising that some wonderful recoveries occurred the writers evidently think that the gospel of the innocuous nature of bullet-wounds has gone too far. They have, in fact, been gradually driven to the conclusion that the great majority of men shot through the small intestine die, and think that the very generally expressed opinion that such wounds are comparatively seldom fatal is but little supported by fact. They are, very properly, emphatic on the fact that, although a bullet-wound is essentially a penetrating or perforating wound, it differs altogether from penetrating wounds inflicted by sharp-pointed instruments. There is always contusion beyond the area of the wound itself and the extent of this contusion varies with the velocity of the projectile and the nature of the injured tissue and, to some extent, with that of the projectile also

After the discussion of such subjects as the typical wounds caused by normal small-bore bullets, entrance and exit wounds, different kinds of bullets, "explosive" wounds, and the clinical course, healing, and treatment of wounds, we come to excellent chapters on Bullet Wounds of Bones and Joints and their Treatment, Injuries of Blood-vessels of the Cranium and Spinal Column, and Thorax, with a special chapter on Wounds of the Abdomen and its Contents—all written with discriminating care and independent judgment and here and there interspersed with original views and practical suggestions. The clinical cases cited throughout the volume strike us as being very pertinent to the subjects in hand. We must not forget to add that the volume is well and copiously illustrated, well got up, and furnished with a good index. After what we have said it is, perhaps, needless to add that we have read the book with pleasure and profit and are glad to be able to express a high opinion of its merits.

Modern Cremation: its History and Practice to the Present Date. By Sir HENRY THOMPSON, Bart., F.R.C.S. Eng., President of the Cremation Society in England since its foundation in 1874. Fourth edition, revised and enlarged. London: Smith, Elder, and Co. 1901. Five plates and other illustrations. Pp. 204. 8vo. Price 2*s.*

THE statistics concerning the cremation of human bodies, cremation societies, and crematoria throughout the United Kingdom and every other European country (except France) and in America have been carefully collected by Sir Henry Thompson and are published in the interesting and scientific little work before us. This book appeared first in four parts more than 20 years ago, but in the third edition (1899) the subject-matter, enlarged and improved, was presented in six chapters and an appendix. This arrangement has been adhered to and 17 pages have been added in the present edition. The volume deals with the subject of cremation in a delightfully lucid and scientific way. An interesting sketch of the history of the English Cremation Society is first given. The society is now 27 years old and among the members of its council have been such men as Sir Arthur Arnold, Sir Charles Cameron, Bart., M.P., Dr. R. Farquharson, M.P., and the Rev. Charles Voysey. Those who approve of cremation will be pleased to observe that in spite of much adverse criticism and even temporary opposition from an unenlightened Home Office the society has flourished and that the number of cremations performed yearly steadily increases. Up to December, 1898, a total of 1283 dead bodies had been cremated at Woking. Up to December, 1900, 1824 bodies had been thus treated and rendered incapable of putrefaction and harmless to the living.

A full account of the deputation sent by the society to wait on Mr. Asquith, then Home Secretary (1893), will be found in the third chapter. A select committee in the lower House was duly appointed to inquire fully into "defects in the present system of death-certification" alleged by Sir Henry Thompson and his friends to exist. The report of this committee completely indorsed the statements brought forward by the society's deputation. A change of Ministry occurred soon after and the question relating to death-certification has been shelved ever since. "This flagrant blot"—to quote from the author's preface—"on the conduct of our social arrangements still exists." As might be expected from a knowledge of the thoroughness of Sir Henry Thompson's scientific researches and observations, the arguments for cremation from a public health standpoint are sound and catholic in view. He makes the surprising statement that upwards of 2000 acres in the metropolis have been used as burial grounds for our dead—acres which might have been sites of residences for our overgrown population or open spaces for the recreation of the masses. The book is not only a scientific exposition of the *pros* and *cons* of cremation, but contains also a detailed account of the crematorium, of the ceremony and process of cremation, and of the exhaustive investigation made in every case of death, lest cremation and burial should be premature, or the crime of secret poisoning should be concealed by the impossibility of a future exhumation

LIBRARY TABLE.

Chemistry and Physics: a Manual for Students and Practitioners By WALTON MARTIN, Ph.B, M.D., and WILLIAM H. ROCKWELL, Jun, M.D. London: Henry Kimpton. 1901. Pp 374 Price 7*s.* 6*d.*—This work belongs to the series of modern text-books edited by Bern B. Gallaudet, M D, demonstrator of anatomy and instructor in surgery at the College of Physicians and Surgeons, Columbia University, New York. The following is the first sentence in the preface of this book: "In the education of medical students a knowledge of chemistry and physics is important, though from a practical point of view it need not be exhaustive." The book is not only not exhaustive, but it is most inadequate. This will be apparent when we mention that both inorganic chemistry and organic chemistry are dismissed in 182 pages. Theory is completely ignored, equations and formulæ are here and there wrong, whilst spelling is not entirely free from fault. We regard the section on physics in a more favourable light, but we know plenty of works which though they deal with the subject concisely and in a way adapted to the needs of the medical student, yet do so in a more masterly manner than is here displayed. The bulk of the illustrations are borrowed from the classic Deschanel. It is almost inconceivable that a work presumably devoted to physics for the special requirements of medical students should devote this much and no more to the "x" rays:—"'X' Rays.—This light from a Crooke's tube, termed radiant by him, has the property of passing through many substances formerly considered opaque while glass obstructs it. This light is popularly known as 'x' rays." This is all—not a word about Roentgen, the discoverer of the rays, and not a word about the use of the rays in medicine and surgery. The book is disappointing.

The Economic Disposal of Towns' Refuse. By W. FRANCIS GOODRICH, A.I. Mech. E London: P. S. King and Son. 1901. Pp. 356. With 75 Illustrations. Price 10*s.* 6*d.*—It is a satisfactory sanitary sign of the times that the disposal of refuse has been brought to such a pitch as to merit discussion in a book of the exhaustive character of the one before us. It is not very long ago that the destructor was unknown, at least as a satisfactory means of disposing of refuse. The evolution of the refuse destructor dates back perhaps about 30 years when, as Mr. Goodrich points out, the destruction of towns' refuse by burning in a furnace was attempted in the north of England, but, as might have been expected, the first furnaces were of a very crude kind, baking rather than destroying the refuse or merely charring or sterilising it perhaps and driving off gases which were a source of offence. The first destructor erected in the vicinity of London, we learn from this book, was that constructed by Mr. Charles Jones, M.I.C.E, which was designed to destroy the gases produced in the destructor cells—that is to say, it consisted of two distinct parts: a furnace and a fume cremator. It is now found, of course, that a fume cremator is superfluous, and the modern refuse-disposing appliance is so satisfactory in its working and in regard to its results as to leave no excuse to our sanitary authorities for "tipping" refuse and leaving it to dispose of itself in offensive heaps as best it may. The construction of destructors has given rise to a new department of engineering and the peculiar problems presented have been overcome with characteristic success We in this country may take to ourselves the credit of being the pioneers of this excellent movement. Mr. Goodrich has made his book more valuable than others that have hitherto been published on the subject because in its pages are described the various methods by which refuse is being dealt with all over the world, and thus the reader is brought into contact with the various difficulties of environment met with, chiefly climatic, in different countries. All the refuse destructors of the world are described, and perhaps connected with these the American practice is the most interesting to study. The work is of a highly instructive and practical character, giving the results of all the systems known where they have been in use or are in use in this country We are glad to note a chapter on the Value of Towns' Refuse for Steam Raising, in which the author enters into the average composition of ashbin refuse, the heating power of ashpit refuse, the average evaporative power of towns' refuse obtained in practice, the analysis of well-known coals used for household purposes, the chemical composition of various coals, the relative efficiency of coals, and the composition of coal ash. The tables recording these results are clearly valuable as affording a guide to the fuel value of all sorts and conditions of garbage. The last chapter contains a few notes on Disposal of Street Refuse, Trade Refuse, and Market Offal. In regard to the disposal of the last-named offensive substances it is evident that in this respect the continental system is ahead of anything which we have adopted here. Speaking of snow the author says that it is scarcely necessary to say that neither in this country nor in America has it yet been found possible to burn snow in destructor cells, yet it is claimed, he says, for at least one American destructor that by its means water can be burned. Mr. Goodrich has spared no pains to collect a vast amount of material with regard to one of the most important branches of sanitary administration. His book may be safely described as a standard work and is of both educational and technical value.

A Syllabus of New Remedies and Therapeutic Measures. By J. W. WAINWRIGHT, M.D. Chicago: G. P. Englehard and Co. 1901. Pp. 230. Price $1.—The aim of this book is good, but unfortunately its usefulness must of necessity be short-lived. It contains a conspectus of the new and chiefly synthetic remedies now having a recognised place in medicine. We may mention as examples lycetol, citrophen, chloretone, nosophen, heroin, and eucaine. The author has done well in collecting clinical excerpts on the value of these new remedies. Practitioners are constantly wanting to know about new drugs of which they have never before heard or of which at least they have had no experience. Since it furnishes information of this kind this compilation of new remedies and therapeutic measures will be valuable, although, as we have said, new preparations are being added to the list of medicaments every day and it is impossible for a book to keep pace with them. Well-written chapters on Anæsthesia, Local and Regional, Animal Remedial Preparations, and Cold and Heat are added.

Scientific Papers and Letters. By A. H. SMEE, M.R.C.S. Eng., F.C.S. Carshalton: William Pile. 1901. Pp. 200.—Mr. Smee has at various times written upon a wide range of subjects and as is shown in the selection of papers before us he is the author of many original ideas. The papers have in part appeared in scientific journals and in part in private letters to scientific colleagues. We have been struck with the method which he describes (in the papers "On the Detection of Germs and Organic Matters in the Atmosphere and the Air we Breathe") for the collection of the moisture in the air, the deposited water to some extent precipitating also the impurities. For this purpose Mr. Smee employs an ordinary glass funnel drawn out to a point at the narrow end and sealed. The funnel is filled with ice, the effect of which is to cool the exterior wall of the funnel upon which the moisture in the air slowly condenses. As this moisture accumulates it trickles down to the point of the funnel and may be collected in any convenient vessel placed below to receive it. The deposited liquid when dried over sulphuric acid on a microscopic slide deposits, he writes, remarkable crystals. The delicate odour of flowers is quite apparent in the aqueous deposit. Mr. Smee considers that nitrogenised bodies are present in a crystalline deposit, and in the crystals obtained from fluids deposited in the wards of hospitals where zymotic diseases exist the curious property was noted that they deliquesce after formation and then recrystallise in other forms. This method, which the author calls "cold distillation," seems to us to be worthy of further study and application, as perhaps it may throw some light upon the nature of the organic impurities of the atmosphere. Other papers in this publication refer to Water-supply, the Chemistry of Albumin and Fibrin, Sounds and Fog, and House Cisterns. On this last subject the author gives a rough sketch of a form of cistern which would meet the requirements, he thinks, laid down by the inspectors of the Local Government Board in their report on the East London Water-supply during the drought. Mr. Smee's cistern would not answer at all because in his sketch the service-pipe is placed at the top. In the event of the main supply being shut off, therefore, it would be impossible to draw off the water in the cistern except by means of the tap which he places below at the termination of a conical end, but then this would contain all the deposited impurities of the water.

The Acute Contagious Diseases of Childhood. By MARCUS P. HATFIELD, A.M., M.D., Professor Emeritus of Diseases of Children, North-Western University Medical School; Professor of Diseases of Children, Chicago Clinical School; Physician, Wesley Hospital. Chicago: G. P. Engelhard and Co. 1901. 8vo. Pp. 142. Price $1.—This little work is practically a *résumé* of the views of the later French and German pediatricians and the compiler has added thereto a few facts gleaned from his own experience. Eight diseases only are dealt with, and these include influenza. In treating the latter disease the author seems to think that every case should be regarded as probably primarily pulmonic in type, and that the medicines should be given with pulmonary complications in view. After attacks of scarlet fever sulphur disinfection is recommended, but we can hardly believe that the author intends to advise this method of disinfecting clothes and bedding or other articles the penetration of which by means of sulphurous acid is extremely difficult. The bacteriology of scarlet fever is somewhat fully dealt with and four rough diagrams are given. There are no other illustrations. In the treatment of variola salol is strongly recommended on the authority of Dr. Begg who, practising in China, has seen a great deal of the disease. He claims that in full doses frequently repeated salol hinders the full development of the pustules, tends to cause them to dry up at an early stage, and diminishes the itching and the need of scratching. A little more care might have been bestowed on the correction of the proof-sheets, for there are a good many mistakes, and two sentences on page 70 are hardly intelligible.

Analytical Records

FROM

THE LANCET LABORATORY.

PRIDEAUX'S PURE MILK CASEIN.

(PRIDEAUX'S PURE CASEIN AND LIFE FOOD COMPANY, LIMITED, MOTCOMBE, DORSET.)

THIS is an admirable product occurring in the form of a perfectly white, light, flaky powder soluble in water. It is separated from the milk by a special process which practically eliminates milk proteid in a pure and soluble state. Its solubility is a valuable feature of the preparation. It is practically tasteless and keeps indefinitely. Our analysis gave the following results which virtually confirm those already published: casein, 86·47 per cent.; lime salts (phosphates), 1·92 per cent.; soda salts, 1·01 per cent.; milk fat, 3·60 per cent.; and moisture, 7·00 per cent. If the moisture be entirely excluded this analysis shows no less than 93 per cent. of pure proteid. Careful testing for milk sugar was attended with negative results. We understand that the best quality of milk is used for the purpose and is obtained from English cows. We have not examined a preparation containing so high a proportion of proteid, and when this is coupled with the fact that this casein is soluble it is obvious that the preparation must possess extremely high food value. It readily peptonises and is therefore easily digestible. Soluble casein may have a very wide number of useful applications directed chiefly towards raising the flesh-forming value of a number of foods. Thus it could be added to bread, soups, beef-tea, tea, coffee, cocoa, and many other foods with undoubted dietetic gain. Moreover, it is free from milk sugar and hence could be used with decided advantage for the preparation of foods for diabetic patients. It contains a certain proportion of fat which, except by a series of laborious operations, and then only on the experimental scale, cannot be separated from the proteid. Soluble casein might be advantageously associated with beef preparations, especially those which are mere extracts. The solution of this casein presents the same characteristics as milk; it is slightly opalescent, but assumes exactly the opacity of milk when common salt or a little alcohol is added to it. Further, on boiling the solution and concentrating it a scum appears on the surface (albumin), just as when milk is concentrated by boiling. Dr. R. Hutchison has suggested[1] the preparation of a diabetic milk by separating from ordinary milk the casein, re-dissolving the proteid in weak alkali, and adding cream and a little saccharin to the product. Prideaux's soluble casein would appear to be excellently adapted for this purpose. Considering that it is the flesh-forming constituent of a natural food and that it is carefully prepared by a special method it must necessarily be a very powerful and concentrated form of nourishment.

TABLOID GALBANUM COMPOUND.

(BURROUGHS, WELLCOME, AND CO., SNOW HILL-BUILDINGS, LONDON, E.C.)

As is well known, galbanum is associated with assafœtida in the pilula assafœtidæ composita, assisting the stimulant, antispasmodic, expectorant, and laxative properties of the assafœtida. The tabloid galbanum compound contains four grains of the active official preparation.

CONCENTRATED CHICKEN SOUP.

(F. W. GODYE AND SONS, NELSON-STREET, BRISTOL.)

This soup is prepared in Ontario and is preserved in tins. We know for transport purposes that tins are most convenient, but we should regard it with satisfaction if this excellent soup could be preserved just as effectively in glass jars. However, a very careful examination of the liquor did not show the slightest sign of metallic contamination. The soup is of excellent flavour, possessing that glutinous property characteristic of freshly prepared chicken soup. The soup contains entire cooked portions of the chicken. It should make an excellent emergency ration and portable food, but, as we have hinted, there is a prejudice against tinned food which is not altogether without a reasonable basis and in the present instance the use of glass vessels would obviate this prejudice. In that case this soup would leave little to be desired.

UNSWEETENED CONDENSED SWISS MILK (EDELWEISS BRAND).

(THE SWISS MILK SOCIETY: LONDON AGENTS, H. GILBERTSON AND SONS, LIMITED, 11, ST. ANDREWS-STREET, HOLBORN-CIRCUS, LONDON, E.C.)

The feature of this excellent milk is, as analysis shows, that it is concentrated to approximately about one-third without the addition of sugar or of any preservative. The milk is quite sterile and keeps well even after the tin is opened. We could find no chemical preservative. The milk is of a creamy consistence and possesses a rich creamy flavour in which only the smallest suspicion of "scalding" taste can be traced. It is recommended on the label of the tin to mix one part of the concentrated milk with two or three parts of water. For the purpose of analysis we adopted the former proportion and the mixture so obtained gave the following results: total solids, 11·30 per cent.—consisting of milk fat, 3·17 per cent.; milk sugar, 4·00 per cent.; proteid, 3·51 per cent.; and mineral matter, 0·62 per cent. This shows that in accordance with the directions for use a milk of good quality is obtained. Especially is it important to add that all the cream is retained. We understand that the concentrated milk is prepared under bacteriological control and supervision, and, moreover, that the cows are fed for at least

---

[1] THE LANCET, June 22nd, 1901, p. 1753.

10 months of the year on pasture and not stall-fed, a statement which is quite consistent with the excellent character of the milk which we examined. The fact that this milk is free from added sugar is an undoubted advantage for many dietetic purposes.

COFFEE AND CHICORY ESSENCES.

(ALEXANDER ELDER AND SON, BEVERHALL-ROAD, EDINBURGH.)

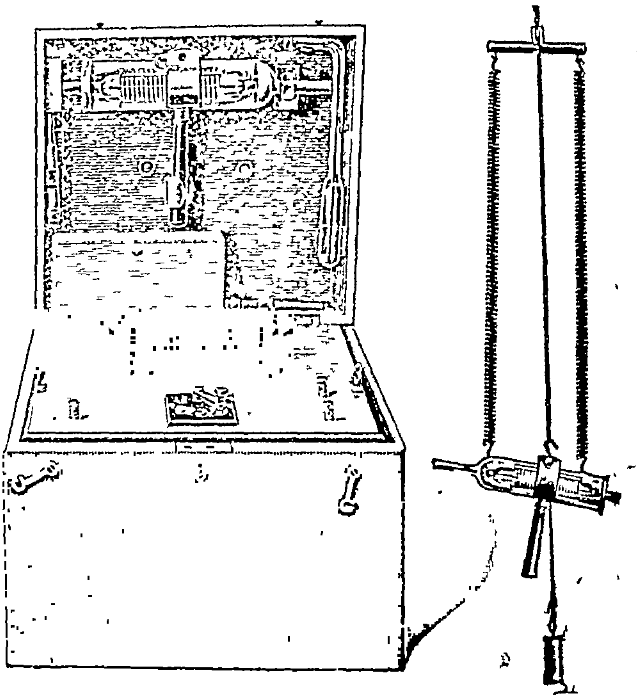
Two coffee and chicory essences were sent to us for examination, the first being sweetened and made syrupy with sugar, and the second containing no added sugar, but a small amount of chemical preservative being added to both. We do not doubt the genuineness of these preparations since we were able to extract from them the aromatic oils of coffee as well as caffeine. The manufacturers have succeeded to a large extent in retaining the agreeable aromatic properties of the freshly roasted berry. Our analyses gave the following results. Sweetened: moisture, 30·37 per cent.; extractives and sugar, 69·63 per cent.; caffeine, 0·22 per cent.; and mineral matter, 1·32 per cent. Unsweetened: moisture, 69 89 per cent.; coffee extractives, 30·11 per cent.; caffeine, 0·48 per cent.; and mineral matter, 2·25 per cent. In our opinion the unsweetened is the better preparation of the two. The analysis of a great number of coffee extracts on the market were recorded in THE LANCET Special Analytical Sanitary Commission on the Composition and Value of Coffee Extracts in THE LANCET of July 4th, 1894, p. 43. It will be found that the preparations now under examination compare very favourably with the extracts then analysed and chiefly in regard to the proportion of the stimulating principle—caffeine.

New Inventions.

MEDICAL OZONISERS.

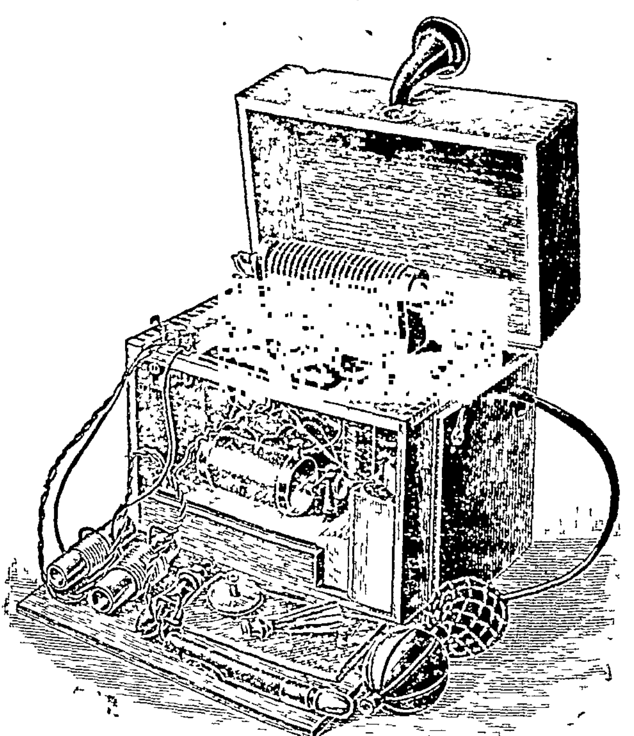
OZONE has had relatively but little application in therapeutics, chiefly, perhaps, on account of the difficulties associated with its production, but now that inexpensive and, moreover, portable apparatus for the production of ozone is obtainable there is no reason why ozone should not be tried more extensively in medical practice in a number of ways in which its well-known powerful oxidising property might be made use of. It is this property which renders ozone an unstable body and in the presence of moisture makes it fatal to germs, and so suggests its useful application in the treatment of wounds, for its cleansing and healing effects are due to this same instability—that is, the ease with which it gives up oxygen in a nascent and powerfully active state. The sterilising power of ozone is well shown when ozonised air is bubbled through water infected with the typhoid bacillus; its decolourising power is also easily shown by passing ozonised air through water of a brown or peaty colour, and it has been suggested that ozone might be used with advantage to bleach public water-supplies which show a yellowish brown tinge due to the presence of vegetable matter. Its destructive effect upon offensive matters, again, may be easily demonstrated by passing ozonised air through water foul with sulphuretted hydrogen. Its freshening effect upon the air of an apartment, a sick chamber, a hospital ward, or a crowded place is soon obvious where an ozone generator is at work. All these remarkable properties suggest how ozone might be used with distinct advantage in medicine and in surgery. It has been used in the form of ozonised air for the purpose of inhalation, exercising a disinfectant action along the respiratory tract and effecting a distinct increase in the number of red corpuscles and thus ministering to an anæmic condition. The simplest way, perhaps, of producing ozone is by means of the electric discharge, although there are other methods, which, however, are not suitable for medical purposes. Amongst the ozone generators which we have examined from time to time, none, perhaps, is so compact or so certain in action as the particular one known as the "Andreoli generator." It is very simple in construction, consisting of a partially-exhausted glass tube with an aluminium wire passing down the whole interior of the tube provided with a terminal for connecting with one of the wires from the induction coil. Outside the tube are a number of parallel coils of aluminium almost completely enveloping the vacuum tube. The pole of the vacuum tube is connected with one wire from the induction coil while the aluminium coil is connected with the other wire. The discharge proceeds silently and a steady production of ozone ensues. The battery power need not be very great, indeed, the whole apparatus complete, including battery coil and generator, may be contained in a portable case. A portable ozoniser answering to this description is illustrated in the accompanying figure (Fig. 1). It is known as the "Alpha medical ozoniser and 'applicator,'" and comprises a battery of

FIG. 1.



The "Alpha" Medical Ozoniser and "Applicator."

FIG. 2.

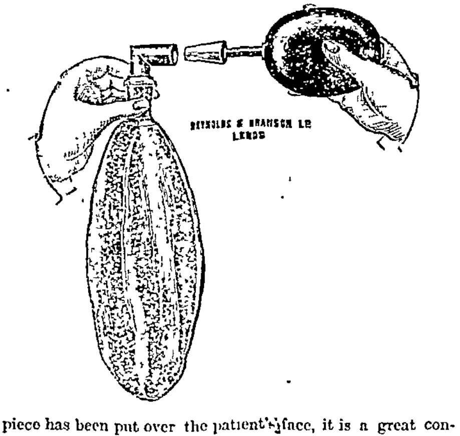


The "Beta" Ozoniser and Inhaler.

four so-called dry cells fitted with a regulating switch, an [illegible], and immediately behind it is the ozone generator. In the lid of the case is seen what is known as the "applicator," which is designed for the application of a stream of ozonised air to suppurating or gangrenous surfaces. On the right of this "applicator" is seen a glass tube which is used for the purpose of forcing ozonised air through water with a view to its purification and sterilisation. To the right of the illustration the "applicator" will be seen suspended on spiral wires provided with a counterpoise, so that the instrument may be suspended from any convenient point out of the way of the operator or patient. All the parts and accessories fit neatly in the case.

Another form of ozoniser is seen in Fig. 2 In this case provision is made for inhaling the ozone produced through a trumpet-like exit-tube fitted in the lid. For this purpose the lid is closed over the generator and air is gently aspirated over the coil from beneath. In this way ozonised air may be inhaled. This apparatus, however, is also an ingenious combination of other electrical applications. Thus, by means of the two switches shown in the illustration the current (primary) can be turned on for actuating a small electric lamp for the examination of the throat or nose or for administering a current (secondary) through the body by means of two terminal handles or by plate electrodes or by wire brush, all of which are shown in the illustration. This handy little apparatus is known as "the 'Beta' ozoniser and inhaler" and weighs only 11¼ pounds, while its dimensions are 10 inches by 6¼ inches by 9¾ inches. We have made a number of experiments with regard to the ozonising properties of this apparatus and with satisfactory results. The effect of ozone upon fœtid air is remarkable—it gives a sense of freshness which suggests its useful application in the sick room. Of course, the amount of ozone obtainable from the tube is proportional to the amount of electrical energy used. By means of a transformer for which special terminals on the ozoniser are provided ozone may be generated in powerful quantities by the alternating current from the main These examples of ozonisers were submitted to us for inspection and trial by Messrs. Allen and Hanburys of 48, Wigmore-street, W.

A SIMPLE FORM OF PUMP FOR INFLATING THE ETHER-BAG INSTEAD OF BY BREATH INFLATION.



THERE are times during the administration of ether when the bag collapses and when it has to be inflated. Then, too, at the commencement of anæsthesia, soon after the face-piece has been put over the patient's face, it is a great convenience to have a bag nearly full of air ready to affix to the ether apparatus Hitherto the anæsthetist has often had to inflate the bag with his own breath—a practice by no means pleasant or advisable either for patient or medical man. With this form of pump the difficulty is easily overcome and already I have found it very useful in my practice. It was shown at the meeting of the Yorkshire Branch of the British Medical Association on March 27th, 1901. It was made for me by Messrs. Reynolds and Branson, Limited, Leeds.

HERBERT J. ROBSON, M.R.C.S. Eng., L.R.C.P. Edin.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY meeting of the Council was held on July 11th, Sir WILLIAM MAC CORMAC, Bart., K.C.B., K.C.V.O., the President, being in the chair.

The PRESIDENT reported the result of the election of three members of Council on July 4th, as already reported in THE LANCET of July 13th, p. 98. Mr. A. W. Mayo Robson, Mr. W. Watson Cheyne, and Mr. R. Clement Lucas were introduced, made declarations in the terms of the oath prescribed by the Charter of 1800, and took their seats as members of the Council.

A report from the Board of Examiners in Dental Surgery was read, approved, and adopted. The chief alterations made in the regulations for the Licence in Dental Surgery are as follows: additional courses in dental bacteriology and dental materia are required from students who enter at a recognised dental hospital and school on or after May 1st next; and the second professional examination is divided into two parts. This latter change is to come into force at once.

A report was received from the Committee of Management, and as arising out of this report the Council referred to the Committee of Management for consideration and report whether or not it is desirable that some alteration should be made in the regulations relating to the preliminary examinations in arts for candidates for the diplomas of the two Colleges.

At the last meeting of the Council a Member of the College was asked to explain his association with two pamphlets. The explanation required was considered by the Council and accepted, but the Council expressed to the Member the hope that he would no longer associate himself with these pamphlets.

A letter was read from Mr. Thomas Bryant reporting the proceedings of the General Medical Council at their late session. The thanks of the Council were given to Mr. Bryant for his services as the representative of the College.

The PRESIDENT reported that on July 4th, the day appointed for a meeting of Fellows, the required quorum of 30 was not obtained, 15 Fellows *only, including five members* of Council, having attended.

Mr. G. H. MAKINS applied for leave of absence from some of the meetings of the Board of Examiners on account of his presence being required at the meetings of the Government Committee on changes in the Royal Army Medical Corps.—Leave was granted.

The best thanks of the Council were given to Mr. Henry Morris for a donation of books; they included seven volumes of anatomical plates and the works of Albinus.

As already reported in THE LANCET, Mr. H. G. Howse was elected *President* and Mr. T. R. Jessop and Mr. F. Howard Marsh were elected Vice-Presidents. The following committees were appointed:—Museum Committee: Mr. Owen, Mr. Morris, and Mr. Cheyne. Library Committee: Mr. Pick, Mr. Page, and Mr. Godlee. Committee for General Purposes: Mr Cooper, Mr. Gould, and Mr. Langton. Finance Committee Mr Butlin, Mr. Tweedy, and Mr. Willett. The following professors and lecturers were appointed:—Hunterian Professors: Mr. Charles Stewart, Mr. Frederick Gymer Parsons, and Mr. William McAdam Eccles. Arris and Gale Lecturer: Dr. Thomas Grigor Brodie. Erasmus Wilson Lecturer Dr. Charles Powell White.

A unanimous vote of thanks was accorded to Sir William Mac Cormac for the manner in which he had for five years discharged the duties of President.

The next meeting of the Council will be held on August 1st.

THE LANCET.

LONDON: SATURDAY, JULY 20, 1901.

The London County Council and Penny Ices.

FOR many years we have pointed out the dangers attending the penny-ice trade. Accidents have occasionally occurred, and serious cases of illness, sometimes followed by death, have been recorded which were traced to the eating of penny or halfpenny ices purchased at the street-corners. The press at large have given publicity to these facts and at least some provincial towns have been moved to take action—notably, the corporations of Brighton and Liverpool. At last the London County Council has followed this good example. So far back as in our issue of August 24th, 1878, p. 264, we described in detail the penny-ice trade and then insisted that it would be comparatively easy to legislate on the subject. We explained that the penny-ice man differed in a remarkable manner from the generality of Englishmen of the same humble class. He was actuated by a much higher ambition and therefore would be more careful not to transgress the law. As a rule, these Italian itinerant street-vendors are very abstemious and thrifty people. They do not waste their money on drinking or other forms of extravagant merry-making. On the contrary, their one object is to save money so as to be able, after from 10 to 20 years' hard work, to return to their own country. They reckon in that time to be able to hoard up enough money to buy a small farm, probably in the Calabrian mountains, with the right of shooting over the neighbouring hills. Thus, the penny-ice man looks forward to ending his days as a landed proprietor and a sportsman. Persons actuated by such an ambition are generally orderly citizens and will not compromise so fair a future by getting in the bad books of the police.

Nevertheless, there is a serious difficulty in the way of enforcing the needed sanitary reform. The shooting licence and the farm can only be purchased if there is a very large profit on the penny ices. On the other hand, if the penny-ice man is compelled to live in a healthy tenement and to make his ices on premises where the surroundings are so well ordered that there shall be no risk of contamination, then it is to be feared that a large share of the profits will be eaten up in rent. So far as possible, therefore, these Italians cluster together, notably on Saffron-hill. They thus not only secure the companionship of fellow-countrymen, but they have close at hand all that they need for their trade. Ice in sufficient quantities and cheap is not to be obtained in all parts of London at four o'clock in the morning. It is at this early hour that the penny-ice man sallies forth with baskets and old bits of cloth or flannel to buy his store of ice. Then he must also find close at hand the milk, eggs, and colouring material that he needs and at once proceed to make his ices. It is only when this is done and the mixture can be left to freeze that he begins to think of breakfast and of dressing himself for his day's outing. Doubtless the fastidious would prefer that he should dress himself properly, and in any case that he should wash himself before making the ices, but this, we fear, is altogether too ideal a conception to be practical. It would necessitate his rising even earlier in the morning or starting later on his rounds—and many of these men go five or six miles, and sometimes even further, before they can reach a place that has not already been secured by some competitor.

The Public Health Committee of the London County Council recently brought up a report which was adopted by the Council and which recommended legislation forbidding the manufacture, sale, or storage of ices in any cellar or room in which there is an inlet or opening to a drain, or in any other place where there is any risk of contamination or infection. Failure to notify any case of infectious or contagious disease occurring among persons employed in this trade would lead to summary conviction and a penalty not exceeding 40*s*. Finally, every ice- "cream" vendor must exhibit on his barrow a notice giving the name and address of the person from whom the ices have been obtained. Many ices are made in small backyards of overcrowded tenement houses. In these yards there is generally one closet, or more than one, frequently in a very filthy condition, and there is a drain in the yard for the rain-water, which is often out of order or which has the trap broken. It is likewise very doubtful whether these yards are systematically swept and cleaned out. Should a law such as that which is now proposed be enforced, where are the ice-men to make their ices? It is not proposed to suppress the penny-ice trade altogether, nor is it desirable, we take it, to create a monopoly in favour of some large establishment that may offer the required sanitary guarantees. Yet somewhat similar monopolies exist with regard to a similar class of men—namely, the piano-organ grinders. These men cannot, as a rule, afford to buy a piano-organ, but must hire it from the middle-man. Cab-drivers also generally have to hire their cabs. From the public health point of view it would certainly be a great advantage if the ices were made in large and properly controlled establishments, a sort of wholesale penny-ice manufactory, where the itinerant penny-ice man could go for his daily supply. But it is to be feared that a great portion of the profit is due to the fact that the penny-ice men themselves manufacture the ices. If their profits had to be shared with a wholesale manufacturer they might have a much longer time to wait before they became landed proprietors in their own country. Yet there is so much economy to be realised in the subdivision of labour and in wholesale processes that something in this direction is perhaps possible. Like all economic revolutions it would, however, cause considerable disturbance and some distress. There are not only the penny-ice men to be considered, but the retail tradesmen who supply what they require, and here the question arises as to whether the ices are always made with suitable ingredients.

When we inquired into this matter we found that though cochineal was generally used to simulate raspberries or strawberries aniline-red crystals were also sometimes employed. With the latter 30 gallons of ice coulds be coloured for 1*d*., while it would cost 1*s*. 6*d*. to colour the same quantity with cochineal. Frozen water and sugar and colouring matter which can be sold as raspberry ice cost about 1*d.* the pint. But the chief demand is for "cream" ices and these cost much more to produce. There must be a little milk thickened with arrowroot, and even though an egg or two may be occasionally employed too many are required to colour the ice economically, and therefore saffron or turmeric is added. But as saffron is about 20 times dearer than turmeric the latter is used when the customers are not over particular. Of course, a little cheap and rotting fruit will greatly "improve" the "delicacy," and some inexpensive gelatin of suspicious origin will give body and consistency to the mixture. Altogether there are various economical contrivances by which the value of the ices can be enhanced, though these are not free from danger to health. Therefore it would indeed be a great advantage if instead of being made in the secrecy of a backyard and in proximity to an overflowing dustbin these widely consumed "delicacies" were manufactured on large and well-managed premises, specially arranged for that purpose, where responsible persons would have a reputation to maintain which it would not pay to lose for the sake of effecting some petty economy. It does not suffice to enact laws condemning unwholesome processes and insanitary surroundings—some thought must be given to the creation of opportunities by which the penny-ice men will be able to observe the new regulations.

The Sanitary State of Hong-Kong.

WE hear from more than one source that the present sanitary state of Hong-Kong is most unsatisfactory, and there is much evidence to show that for many years past very little has been done in the way of improving the state of affairs. On the contrary, in some directions changes have taken place for the worse. It seems that as long ago as the year 1875 the late Dr. AYRES reported on the sanitary condition of the colony in a most unfavourable sense, but finding that no improvement resulted from his endeavours in that direction he was led to give up a hopeless struggle. A few years later, in 1882, Mr. OSBERT CHADWICK made another report, which was in due course printed and presented to both Houses of Parliament. Mr. CHADWICK recommended amongst other things that 600 cubic feet of air space per head should be provided in all rooms which were sub-divided into cubicles and that the ground surface of buildings should be covered with concrete. The latter recommendation was enforced after the plague epidemic of 1894, but the former recommendation has not even yet been adopted, and the amount of air-space insisted upon is at the present time only 400 cubic feet per individual. Many other alterations were advised by Mr. CHADWICK, but they have not been carried out Some of the most important of the improvements which he recommended had reference to the dwellings of the poorer classes—that, for example, the houses should be provided with continuous back alleys, and that insanitary properties should be purchased and demolished. Mr. CHADWICK concluded his report with these words: "I trust that even should the suggestions be found undesirable or impracticable my report will show the necessity for strong and complete measures of sanitation, and I trust that they will be undertaken for the immediate benefit of the public health without waiting for the necessity to be demonstrated by the irresistible logic of a severe epidemic." Twelve years later, on the outbreak of an epidemic of plague, the necessity which existed for the reforms was abundantly proved.

The attention of the inhabitants of Hong-Kong has lately been strongly directed to a consideration of the conditions under which they have long been and still are living. The presence of bubonic plague has impressed them, and a series of trenchant articles written by Mr. ALFRED CUNNINGHAM has apparently for the moment caused their chronic apathy to be replaced by a feeling of excitement approaching panic. The articles have been republished in the form of a pamphlet[1] which contains, also, a reprint of leading articles bearing upon the subject which have appeared in the *Hong-Kong Daily Press* and the *China Mail*, and some letters which have appeared in the former paper. There appears to be no shadow of a doubt that the drainage of Hong-Kong is inadequate, that there is not enough water to flush the sewers, and that the soil is saturated with decomposing fæcal matter. A Sanitary Board exists, but this Board has no administrative functions, and the recommendations of the Board are sometimes wholly ignored. The responsibility for the present state of things therefore rests with the Executive Government—that is to say, with the Colonial Office. Dr. F. W. CLARK, the medical officer of health of Hong-Kong, has lately (May 30th, 1901) succeeded in getting the Sanitary Board to pass two resolutions recommending the Government to make arrangements for flushing the sewers. The first resolution was as follows:—

> "That the board recommend the Government to utilise all the fresh water which now runs to waste in the trained and untrained nullahs of the city by building dams and forming tanks for the automatic flushing of the sewers and storm-water drains."

The resolution is so obviously sensible that it seems at first sight curious that Dr. CLARK should have had any misgiving as to the effect of such a recommendation passed by the Sanitary Board. It is in this connexion that we go into detail in regard to the matter. Dr. CLARK in the course of his speech said that the position of the Board recalled the parable of the importunate widow, and the resolution was strongly criticised by the president of the Board, the Hon. W. CHATHAM, who presumably represented the Government as an official member. The ground of opposition of the official nominee was that the nullahs were sometimes dry and that water was therefore not always available, and that it was especially liable to be deficient in quantity when it was most required—that is to say, during the hot season. But it must be said that Dr. CLARK did not propose to rely solely on this source and his next resolution (as he pointed out, the necessary corollary of the first) was that a supplementary supply of sea-water should be pumped to make good the deficiency. The resolution was as follows:—

> "That the Government be requested to again consider the question of the flushing of the sewers and storm-water drains

---

[1] The Need of Municipal Freedom in Hong-Kong, by "Scrutator," with articles and correspondence thereon, reprinted from the *Hong-Kong Daily Press* and *China Mail*. Hong-Kong: The *Daily Press* Office, 14, Des Vaux-road. 1901.

of the city with sea-water pumped from the harbour to suitable storage tanks."

Both these recommendations were passed and the Board then discussed a third motion, having regard to storm-water drains. Dr. Clark moved :—

"That the Government be requested to consider the advisability of trapping all inlets to the storm-water drains, in view of the fact that the 'report on the latrine and urinal accommodation of the city and its connexion with the fouling of the storm-water drains,' forwarded to the Government in 1899, showed that the contents of the storm-water drains are as foul and in some cases even fouler than the contents of the sewers."

The fact that such advice on the elements of sanitation has to be forced on the attention of the Government of Hong-Kong year after year clearly shows the existence of a state of things which is discreditable to the authority responsible and dangerous to the community.

Mr. Cunningham's articles, to which a brief allusion has already been made, are vigorously written. They display in some places a warmth of feeling which it is not necessary or desirable that we should imitate, but which is doubtless quite excusable in one compelled to live under such uncomfortable conditions and suffering daily and hourly from the neglect of the governing authorities to carry out their obvious duties. It cannot be pleaded that the colony is too poor to be able to afford to pay the expense necessary to ensure efficient sanitation. Sir Henry Blake, in his report on the financial condition of Hong-Kong, lately pointed out that the condition of the colony was "most flourishing—that its future promised to be bright and that there was a large excess of revenue over expenditure." But in almost every respect the general management of the colony appears to be open to improvement. The deficiency of the water-supply has been mentioned, but in addition to this the inhabitants have other causes of complaint. The roads are bad, the town is overcrowded, and the sanitary staff is undermanned. "The sanitary staff," says Mr. Cunningham, "consists of a doctor and about 20 inspectors who are not paid sufficiently well to induce a man with sanitary training and experience to accept such a post." A single sanitary officer is certainly not enough ; it is necessary that he shall occasionally be away on leave, and it is stated that it happened that he was away lately on the outbreak of an epidemic of plague. The condition of the dwellings of the poor in Hong-Kong forms a constant source of danger to the whole town. The houses are greatly overcrowded ; they are ill-lighted and insufficiently ventilated. Vested interests are treated tenderly in Hong-Kong, and Mr. Cunningham does not darkly hint—he plainly says : "The unofficial representatives in the Legislative Council are concerned in these vested interests." Such an accusation cannot be allowed to pass without inquiry. The health of the people of Hong-Kong depends to a large extent on the sanitation of the place. Cases of plague must in the ordinary course be occasionally imported. The spread of the disease in the town will depend largely on its hygienic conditions. Overcrowding and insanitary dwellings will have their effect in increasing the number of cases and the mortality. It is said that the overcrowding is actually encouraged by the action of the "unofficial representatives of the executive council." Such a statement, publicly made, widely spread and uncontradicted, certainly deserves the attention of the Colonial Secretary.

This alleged scandal forms but one part of the subject. Whatever the truth may be about this particular accusation we are more concerned to show that there is no doubt that the whole question of the sanitation of Hong-Kong requires a thorough and impartial investigation and prompt action that the place may be put into a sanitary and a civilised state with the least possible loss of time. Dr. Clark, the medical officer of health, has apparently done and is doing the best he can under the most trying conditions. He requires support and help. Nothing is more discouraging to a man whose heart is in his work than a knowledge that he has not the power to ensure that what ought to be done shall be done, and done quickly. The persistency of the importunate widow was not an unfeminine characteristic, but a Sanitary Board should be invested with some power more immediately effective than importunity.

The Public Hospital and the Private Individual.

The voluntary support of charitable institutions has always appealed strongly to the generosity of Englishmen. It is well in accord with the national character that men who have inherited a great name and great wealth, or who have amassed large fortunes through commercial enterprise, or, which is rarer, who have met with exceptional professional success, should spare a portion of their wealth to some benevolent institution in which they are interested and of the excellence of which they are convinced. With different peoples the expression of philanthropy, as of other qualities, takes different forms. In Great Britain it is natural and congruous for such expression to take the form of unostentatious substantial benefit conferred upon less fortunate or suffering fellow-citizens. In ancient Rome the victorious and enriched conqueror thought that he could in no way better benefit his fellow-men than by providing some gigantic spectacle. A day's amusement seemed the appropriate offering due from his aggrandisement to his humbler fellows, and the plaudits of a multitude gratified his ears when at his personal expense some score of gladiators were butchered to make a Roman holiday.

Even in later days than those of classic Rome the love of ostentation that is deep-rooted in the nature of many peoples has led successful men to demonstrate their public benevolence by providing some exceptional opportunity for general festivity and enjoyment. But the sober and solid Anglo-Saxon character prefers more lasting benefits—to endow a hospital, to provide a free library, or in some way or other to advance the public good on a large scale appeals to us as a finer and more satisfactory expression of practical goodwill towards our fellow-creatures. In this way many a person, whose name is perhaps unknown except in the small limits of his native place, has conferred the truest benefits on successive generations of fellow-townsmen. And of men who have on a huge scale advanced the public welfare by tremendous efforts of philanthropy and self-sacrifice Great Britain has provided probably more than any other one country as yet, though undoubtedly the United States of America run us close. In every class, in every sect, in every social arrangement there will be found among us some name piously remembered for great philanthropic exertions. The political and religious freedom of the country, indeed, has fostered a noble competition of unselfishness and stimulated efforts that are apt to languish where State provision is too predominant. It cannot for a moment be maintained, then, that there is a lack of charitable feeling in Great Britain, or that men of wealth are chary with money when public benevolence is needed, and yet a review of the financial position of some of the great London hospitals might well suggest the opposite conclusion. To be in debt is almost the usual condition of a large general hospital. Its name may be a byword for skill and kindness, and thousands of poor folk yearly reap benefits within its walls. Great physicians and surgeons may have been fostered in its wards, and the richest and the noblest may have had reason to bless the institution where such abilities have been developed. Is it not a paradox that institutions such as these should have constantly to beg for money to continue their very existence and to seek alms that they may be able to confer their blessings on the sufferers of the city? If any gifts deserve SHAKESPEARE'S beautiful epithet "twice blessed" most assuredly they are those that help the needs of a great hospital. Here it is a double work that is constantly going forward. It is not only that the sick poor are being ministered to, but day by day the teachings of experience are being given to students in whose hands mainly lies the future physical welfare of the nation.

The individual rarely realises how much he may owe to the opportunities for training that can only be provided by great hospitals. Such reflections as we have expressed must have assuredly been in the mind of Lord PORTMAN when he gave his generous thank-offering of £1000 and a yearly subscription of 10 guineas to Guy's Hospital. Lord PORTMAN had been ill, and with his contribution to the funds of Guy's Hospital he wrote a letter stating that he owed his recovery under Providence to the medical men and nurses all of whom had been trained at that institution. Here is such a proof of gratitude and generosity as cannot be too widely known or too warmly praised. We should have no need to wonder whether we can provide on this side of the water a philanthropist of the vast power and the patriotic spirit of certain Americans if Lord PORTMAN'S example were but to be generally followed by the many men of wealth and position who can well afford to walk in his steps. Let those who have the wealth and the opportunity realise that their duty is not really finished when they have paid their medical man's account, but that something is, indeed, due from them to the hospital which sent him to their aid properly equipped for the service which they need. Such thank-offerings as this of Lord PORTMAN resemble, but are more than, the votive offerings hung upon the walls of the temple by mariners saved from shipwreck. They are prompted, no doubt, partly by feelings akin to that reverent gratitude of old, but with the enlightenment of a later age they not only ease the conscience of the donor but they also go far towards securing an equally happy relief from suffering for others who may be stricken. Very many rich men and women fall sick, recover, and are grateful to the medical men under whose care their illness has had a happy termination. What proportion, we wonder, ever found in their recovery a reason for subscribing in some way to a hospital? Yet it needs but little reflection for them to see that such a call upon their charity is really made with all justice. We do not disregard the large number of charitable gifts that are actually made. We hold that this country can point to no worthier national emblems than to the many great hospitals which bear the proud legend, "Entirely supported by voluntary contributions." What we do insist on, though, is the fine particular opportunity for charity towards hospitals—an opportunity frequently arising and too seldom employed—that Lord PORTMAN has demonstrated to all who may be similarly placed by his contribution to the funds of Guy's Hospital.

Annotations.

"Ne quid nimis."

PORTABLE ISOLATION AND EMERGENCY HOSPITALS.

A BILL has been adopted by both Houses of Parliament which gives local authorities the power to transfer to the county councils any isolation hospital which they may have built. The object of the Bill is evidently to encourage the construction of such hospitals by extending the area on which the rates to meet the cost may be levied. So far so good; but this does not cover all the necessities of the case. There are two requirements to be considered. First, there are the ordinary cases of infectious disease which need isolation and which occur under what may be termed non-epidemic conditions. It is a comparatively easy matter to make the necessary provision for these. Secondly, there is the possibility of an exceptional, virulent, and widespread epidemic. It is quite certain that the great majority of sanitary authorities are not prepared for such a contingency. There may be one or more isolation hospitals, but they would be insufficient for a really widespread epidemic. As an example of our meaning we may take the epidemic of typhoid fever at Maidstone. During the last two weeks of September, 1897, 509 cases of typhoid fever were notified and it is unreasonable to suppose that a small town of only 32,000 inhabitants, which in no wise anticipated such a severe and sudden epidemic, should have been provided beforehand with isolation hospitals large enough to hold so considerable a proportion of the population. The result was that the Salvation Army barracks, several schools, and other buildings had to be converted into emergency hospitals. This, of course, necessitated some delay, which was mischievous, and the buildings, when secured, had to be fitted up, which meant further delay. Finally, as these buildings were not erected for hospitals they were naturally not suited for the purpose. Still, this was the best that could be done under the circumstances. But cannot something better now be organised in view of future emergencies of this description? Possibly some central authority or authorities—such as the county councils—might lay up a store of portable field hospitals. These hospitals might be built of varying sizes, holding from some 12 to 50 beds each, and any number of them might be set up in rapid succession one by the side of the other. Sanitary authorities would then only have to construct permanent isolation hospitals for what might be regarded by the Local Government Board as the reasonable needs of the district. But any such temporary provision as is here in question should not be allowed to prevent—as conceivably it might—the provision of suitable permanent structures and the acquirement of the necessary site or sites upon which the temporary structures could be erected. Assuming, however, the suggestion to be carried out a telegram to the central authorities could be sent and the hospital, with all the accessories, could be on the spot within 24 hours and could be erected and ready to receive patients in the space of another 24 hours. As the epidemic spread so would more hospitals be sent for. When the epidemic was over the hospitals could be pulled down, disinfected, and sent back with equal promptitude, although we have grave doubts whether, in the case of certain diseases, disinfection could be properly carried out, and such hospitals with the wear and tear to which they would be subject would soon cease to be thoroughly satisfactory. Moreover, in the winter months difficulty might be experienced as regards heating. In summer some such provision as is suggested is already held in readiness in the shape of tents by certain authorities. The local authorities would pay a rent for the use of these hospitals which, in the course of time, might repay the capital expended in their purchase. Assuming the practicability of this scheme efficient and sufficient accommodation might be provided with great promptitude to the poorest local authorities. Under such circumstances there would be no excuse for delay and inefficiency in isolating the victims of an unexpected and far-reaching epidemic.

MYASTHENIA GRAVIS WITH LESIONS FOUND IN THE THYMUS GLAND AND MUSCLES.

CONSIDERABLE attention has been lately paid to the condition known as myasthenia gravis, but up to the present time no pathological change has been demonstrated either in the nervous system or muscles to account for the condition. In the *Neurologisches Centralblatt* for this month, however, there is published by Laquer and Weigert a case in which definite changes were found in the muscles. The case is that of a man, aged 30 years, who in 1896 suffered from giddiness, palpitation, and feeling of weakness after exertion. In 1900 he experienced difficulty in raising the arms and at the same time had drooping of the right upper eyelid; a few months later there was marked weakness in chewing and also in the muscles of the larynx, and after prolonged reading aloud the patient became hoarse. The muscular weakness was well shown in the deltoid muscle. After examination of the patient a severe attack of cardiac failure occurred from which he was with difficulty revived. After four months' improvement took place and he returned to work, but in four weeks he again became weak, with difficulty in swallowing, nasal speech, and weakness of the neck and lumbar muscles, so that he could no longer raise himself. The muscles gave the myasthenic reaction The difficulty in respiration became distressing owing to the paresis of the diaphragm and intercostals, but the patient remained fully conscious till the time of death. At the necropsy there was found in the situation of the thymus gland a tumour about five centimetres in length and breadth and about three centimetres in thickness. It lay in close connexion with the pericardium but did not involve the great veins. From the lungs a tag had become firmly adherent to the tumour. The nervous system and the muscles appeared to the naked-eye to be normal On microscopical examination the tumour was found to consist of small cells, lymphoid cells which form the chief part of the normal thymus, larger epithelioid cells also normally present in the thymus, and Hassall's bodies. In many of the veins within the tumour the walls were destroyed and the tumour cells had grown into the lumen and the same appearance was also present in the arteries. But of most exceptional interest was the condition found in the muscles. In the deltoid and diaphragm it was found that at many points both in the sheath of the muscles and between the muscle fibres there was a great invasion of small lymphoid cells which closely resembled those found in the thymus tumour and to a lesser extent the larger epithelioid cells were also present. The muscle fibres themselves, however, appeared to be normal. In the heart muscle similar foci of cells were found, but much less than in the skeletal muscles. Nothing abnormal was found in the nerves, spinal cord, or brain. The combination of myasthenia gravis with disease of the thymus is noteworthy, and though the same condition may have been present in some cases it is hardly likely that such marked changes in the muscles should have escaped the observation of those who have carefully examined these cases microscopically.

DEATHS FROM LIGHTNING.

Two deaths are reported from Sussex during the thunderstorm on July 6th. Both victims were agricultural labourers and were at work in the fields at the time the storm burst over the district. When the rain came on one sought shelter in a shed situated under some trees, the building having a corrugated iron roof. The lightning struck the building. The labourer was also struck and according to the evidence of the medical witness it was his opinion that the lightning left the deceased by a chain which hung out of his pocket and to which two knives were attached. Rigor mortis set in quickly. In the other case the victim was seeking shelter when he was struck down. He was found in a field drain. His clothes were smouldering. The skin on the right side of the face resembled the condition found in the second stage of burning. The body was scorched in places. Both deaths occurred within a few miles of each other in the Ashdown Forest district.

INCREASING STERILITY OF AMERICAN WOMEN.

DR. GEORGE ENGELMAN of Boston read a paper on the subject of the increasing sterility of American women at the annual meeting of the American Medical Association held in June, basing his conclusions upon numerous cases carefully investigated by himself, the conclusions being confirmed by independent investigators such as Dr. Wilbur of Michigan, Dr. Abbott and Dr. Kuszynsky of Massachusetts, and by the studies made by Dr. Chadwick of Boston of the records for that city of the eighteenth century. The various results closely conformed to one another and substantiated the accuracy of the whole. The main facts and conclusions were as follows. 1. The sterility of women has increased, and their fecundity has diminished, in the United States to an excessive degree of late years. Thus, in the eighteenth century 2 per cent. of American women are recorded as sterile, while the average fecundity was five children per married woman. "At the present day the sterility of the American woman is greater, and her fecundity less, than that of the women of any other nation except France." Thus, in St. Louis, 21 per cent. of women of the labouring classes are sterile, the proportion rising to 24 per cent. among women of the higher classes. In Massachusetts the ratio is 20·2 per cent generally for women, and in the city of Boston it is 23·7 per cent. in the labouring classes. 2. The fecundity of American women was five children per family in the eighteenth century, 4·5 in the beginning of the nineteenth century, "and now at the end of that century it is between 1·8 and 2·1 per family." The exact figures are 2·1 in Missouri, 1·8 in Michigan, and 1·8 in Boston for native American women. With regard to occupations and professions, the interesting fact is recorded that fecundity is lowest amongst women graduates of colleges, the proportion being 1·3 per woman. 3. Comparing these figures with those obtained from the immigrant Irish population, it is found that a high ratio of fecundity prevailed among Irishwomen, the figures being 4·2 for St. Louis, 3·5 for Boston, and five for Michigan. For German women the figures were also high—viz., 3·4 for St. Louis and six for Michigan. The fecundity for all female foreigners in Massachusetts was 4·9. 4. Dr. Engelman records his conviction that an increase of secondary or artificially induced sterility (prevention of conception by chemical and physical measures) is largely responsible for the results amongst American women. Miscarriages, too, are correspondingly frequent—viz., 10 miscarriages on an average in 27 labours among native-born American women, the proportion being the same among negro women. There is not, observes Dr. Engelman, an increase of primary sterility from gonorrhœa, utero-ovarian disease, and the like among American women, thus confirming the previous conclusion that the increase of sterility was due to artificial measures and not to primary disease 5. The ratio of primary sterility in American women during the eighteenth century was 2 per cent., that of Russia is at present 2 8 per cent., and of Norway 2·5 per cent., these figures giving the average proportion in peoples of good moral and physical health. Dr. Engelman concludes that wilful and self-inflicted sterility is the cause of the relatively low fertility of women in America and other countries, and affirms his conviction that the ultimate results are an increase of suffering in women who give themselves up to it, apart from the national evils which may follow in the train of depopulation should the practice become more numerically prevalent and compensating causes be removed.

YERBA MATÉ AND AFTERNOON TEA.

A CHERISHED British institution is, it seems, in danger, if not of abolition at all events of considerable, and possibly of fundamental, modification. "At the 'five-o'clock,'" says Dr. Dedet in the *Archives de Médecine Navale* for June, "the American herb *maté* is about to become the substitute of tea, or of all other refreshing beverages." How and when the popular refection known as "five o'clock tea" first came into vogue is not so clear as might, perhaps, be expected. As in some other institutions of lesser, and of greater, importance the origin of the agreeable function is more or less wrapped in obscurity. According to some authorities lawn tennis and the practice of indulging in the cheering cup of an afternoon stand to each other in the relation of cause and effect, whereas in the opinion of other equally positive observers the custom of post-meridian tea-drinking is referable to the more remote period when the lately resuscitated game of croquet began to invade our grass-plots However this may be, Dr. Dedet desires to sound a note of warning before the substitution which he announces shall have become an irrevocable fact. It was in 1874, while serving in the French navy, that he made the acquaintance of maté for the first time. His ship was stationed at Montevideo and in the *salons* of that lively South American city it was then usual to inhale the vapour of a simmering (*mijotant*) infusion of the leaves from a *bombilla* or narrow-mouthed vessel through a tube ending in a globular mouthpiece. The apparatus apparently circulated amidst the company from mouth to mouth, just as the pipe of peace used to circulate when Red Indian braves were assembled in conclave. At that time maté was unknown in Europe, even as a medicament, but since then, according to Dr. Dedet, it has become known as a first-class *agent d'épargne* and cardiac tonic, with possibly febrifuge qualities as well. An analysis made by M. D. Parodi shows that in 1000 parts of yerba maté (ilex paraguayensis) there are 40 of caffetannic acid, seven of caffeine, with smaller quantities of resin, fat, and essential oil. In people who suffer from diseased kidneys the employment of maté is likely to give rise to hæmaturia. Dr. Dedet had recently a patient at Martigny-les-Bains, an ambassadorial attaché, aged about 40 years, who was accustomed to drink an infusion of 30 grammes of maté in 1000 of water "to enable him to work at night." The diplomatist was a martyr to oxaluria, and by a process of exclusion his disability was unmistakeably brought home to the infusion. At once he abandoned the habit, whereupon his symptoms improved, and at the end of 12 months he was able to report himself completely free from all nephritic trouble. "I think," says Dr. Dedet in conclusion, "that like coffee, tea, &c., yerba maté should be interdicted in persons whose kidneys are defective. If this plant should enter further into European alimentation cases in support of mine will no doubt be recorded. I publish mine to open the road."

PUPILLARY DISTURBANCES IN MENTAL DISORDERS.

AN interesting contribution to this subject has been published in a recent *Thèse de Paris* by Dr. Roger Mignot. Apart from the attention devoted to the clinical study of the pupillary symptoms in general paralysis, but little has been done hitherto in this direction as regards other mental disorders. After a lengthy physiological description of the nervous mechanism which subserves pupillary reflexes Dr. Mignot points out that even as regards general paralysis different authors have arrived at varying conclusions. Thus, to speak only of the pupillary reflex to light, Thomsen and Mendel found alteration of this in 47 per cent., whereas Francotte found it in 88 per cent. of cases of general paralysis. To prevent difficulties in collating results it was necessary that the same technique should be adopted under conditions as nearly similar as possible. Thus Dr. Mignot found that among 22 cases of advanced general paralysis inequality of the pupils was met with in 63 per cent., *abolition of the light reflex in 77 per cent.* and diminution in 22 per cent., and alteration of the accommodation reflex in 50 per cent. As regard non-paralytics, the statistics of authors differed. Oebeker found inequality of the pupils in 2 per cent. and Thomsen found immobility of the pupils in 2·1 per cent. Verga and Castiglioni regarded pupillary disturbances as not special to any form of mental alienation and found them in 74 per cent. of cases of insanity generally. Dr. Mignot from careful and repeated observations concludes that pupillary disturbances are not infrequently met with in organic dementia, senile dementia, paranoia, degenerative insanity, intermittent insanity, and the alcoholic insanities. He confirms the observation of Kraepelin that in dementia præcox mydriasis is frequent (30 per cent. of cases). He moreover shows that pupillary inequality may be met with in 32 per cent., disorder of the light reflex in 62 per cent., and of the accommodation reflex in 12 per cent. of cases of dementia præcox. Characteristics of the latter disorder are the variability and alternation of such pupillary changes which may be present in one form now and be altered to-morrow. Among 12 sufferers from senile melancholia alterations of the light reflex were found in 11 cases, this reflex being found to be absent on occasions in two cases. He concludes that while alterations of the pupillary reflexes are frequent and progressive in general paralysis, organic dementia, and senile dementia they are of a changeable and variable character in the other psychoses above mentioned, especially dementia præcox and senile melancholia.

THE ANNUAL MEETING OF THE MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

THE sixtieth annual meeting of the Medico-Psychological Association of Great Britain and Ireland will be held in the Medical School of the Queen's College, Cork, on Thursday and Friday, July 25th and 26th, under the presidency of Dr Oscar T. Woods, who will deliver an address and distribute medals and prizes on the opening day at 2 P.M. After the President's address the following papers will be read. Mr. John Carswell, Convener of Committee on Inebriates of the Corporation of Glasgow, on the Working of the Inebriates Act; Dr. Thomas Drapes, medical superintendent, District Asylum, Enniscorthy, Ireland, on Insanity and Phthisis; Mr. Michael J. Nolan, medical superintendent, District Asylum, Downpatrick, on Residual Lunatics and Recent Legislation; Dr. F. W. Edridge-Green, London, on Evolution of the Colour Sense; Mr. E. D. O'Neill, medical superintendent, the Asylum, Limerick, on the Superannuation Question— its Effect on Asylum Officials, with Suggestions for further Legislation on the Subject. On Friday, July 26th, commencing at 10 A.M., Professor Dixon and Professor Bergin will read a paper on Stereoscopic Radiography and Dr. Joseph Shaw Bolton, Woodford Bridge, will give a lantern demonstration on Gross Lesions of the Cerebrum; Dr. George T. Revington, medical superintendent, Central Criminal Asylum, Dundrum, Ireland, will read a paper on Mental Conditions Resulting in Homicide; and Dr. W. C. Sullivan, H.M. Prison, Pentonville, London, will make a communication on Crime in General Paralytics. At 2 P.M. Dr. John Keay, medical superintendent, District Asylum, Inverness, will initiate a discussion on the Care of the Insane at Night; Dr. A. R. Urquhart, physician superintendent, James Murray's Royal Asylum, Perth, will deal with the Effect upon Patients of Changes of Asylums; Dr. Daniel F. Rambaut, assistant medical officer and pathologist, Richmond District Asylum, Dublin, will read a paper entitled a Case of Cerebral Hemiatrophy; and Mr. R. R. Leeper, resident physician, St. Patrick's Hospital, Dublin, will take for his subject Three Cases of Melancholia presenting Symptoms of Unusual Clinical Interest. The paper will be illustrated by microscopic specimens and photographs. The social arrangements include an "At Home Day" by the President, Dr. Oscar T. Woods, and Mrs. Oscar Woods, on Friday, July 26th, from four to seven o'clock at the District Asylum, Cork; and an excursion to Killarney on Saturday, July 27th. The annual dinner will take place at the Imperial Hotel, Cork, on Thursday, July 25th, at 8 P.M.; tickets £1 1*s.* each. The address of the honorary secretary is 11, Chandos-street, Cavendish-square, London, W.

THE LONDON SCHOOL NURSES SOCIETY.

THE annual report of the above society for the third year of its existence has just been issued. The object of it is to supply carefully trained nurses to inspect the children in London Board schools with regard to such infectious diseases as ophthalmia and "sore heads," whether the latter be due to tinea or pediculi or other forms of disease affecting the hairy scalp. We learn from the report that according to a statement by the chairman of the London School Board made on Oct. 4th, 1900, the society "sends qualified visiting nurses to the poorest schools to attend to the small ailments of the scholars on the principle that there is no more sure way of securing the health of the people than to arrest small ills at the beginning." We do not quite understand whether by the word "attend" the chairman meant "treat," or whether it is simply that if the nurse finds a child with sore head or eyes she should warn the mistress as well as the parents of the child that they should have the disease medically attended to. If the nurse prescribes treatment we should say that she was going beyond her duty, but if she simply acts as a kind of sanitary inspector we think that the work is worthy of all praise. We observe that the society is supported by voluntary contributions and that the number of schools visited regularly is 63, of which number six are apparently not under the School Board. The remaining 57 we gather are those under the Board and we cannot see why a body which demands by "precepts" a sum of over two millions out of the pockets of the ratepayers, a large proportion of which is wasted upon education which is by no means elementary, should not be able to supply the sum of £500 which, according to the report, is all that the London School Nurses Society needs. To provide means for the examination of sore eyes and sore heads is not nearly so romantic an occupation as issuing precepts for continuation schools and the higher grade education; it is, however, infinitely more useful and probably even that school board bogey Mr. Cockerton would not make a surcharge if the Board were to vote a contribution to the London School Nurses Society.

THE MIDWIVES BILL.

ON June 26th the eighth annual meeting of the Association for Promoting the Compulsory Registration of Midwives was held at 47, Cadogan-square. Lord Balfour of Burleigh, who moved the adoption of the report in his private and unofficial capacity, made a speech upon the matter which is dear to the heart of the association, which speech was reported in our issue of July 6th, p. 46. The association was advised to bring up the question again next session and there is not the slightest doubt that they will do so. We would remind our readers that with regard to this matter there must be no attitude of *laissez faire*. The promoters of the Bill are earnest men and women who know what they want. The medical profession, although some four-fifths of the English practitioners who would have been affected by the Bill introduced last year, had it passed, were against the Bill, yet do not seem to have any very clear idea of what they do want. There is a general consensus of opinion that the present state of matters, by which any woman, no matter how ignorant or unclean, may attend her sisters in childbed, is indefensible. But the difficulties of formulating an alternative and workable system are extreme. When Mr. Tatton Egerton's Bill passed its second reading, which it did on March 9th, 1900, we set ourselves to point out in our leading columns[1] the various modifications which we considered indispensable. As it turned out the Bill never arrived at the third reading and so never got a place upon the Statute Book. But the members of our profession should remember that the subject has by no means been dropped and that in all probability the next session of Parliament will see Mr. Tatton Egerton's Bill, or one very similar to it, introduced again.

A DEARTH OF ASSISTANT MEDICAL OFFICERS.

AT a meeting of the Metropolitan Asylums Board on Saturday, July 13th, the Hospitals Committee reported that owing to inadequate responses to advertisements they were experiencing considerable difficulty in filling vacancies in the medical staff of the hospitals service. The committee believed that the board were not singular in that difficulty, for they understood that the dearth of candidates was felt by many other authorities. The supply of qualified men was evidently falling short of the demand, and that fact appeared to be mainly accounted for (1) by raising the standard of the examinations; (2) by the extension of the students' curriculum to five years; and (3) by the substitution of qualified for unqualified medical men as assistants. Moreover, as was well known, a very large number of medical men had taken duty in South Africa in connexion with the war, many of whom would probably remain there. At the present time the committee were not in a position to suggest a remedy for the difficulty referred to, but with the busy season of the year upon them it was possible that an emergency might arise which would require to be dealt with in an exceptional way and they therefore felt it their duty to ask for the powers set forth in the following recommendation—viz.: "That during the period of the summer vacation special powers be given to the Hospitals Committee to deal in such manner as they may think necessary with any emergency that may arise in relation to medical attendance upon the infectious sick in the hospitals of the Board, a report being made to the Board by them upon any measures which they may have taken in pursuance of this authority." The recommendation was agreed to.

---

[1] THE LANCET, March 17th, 1900, p. 783.

THE CHAIR OF PATHOLOGY IN THE UNIVERSITY OF SYDNEY, NEW SOUTH WALES.

As will be seen from a notice in our advertisement columns the chair of pathology in the University of Sydney is vacant and applications for it are invited. The salary, a fixed one, is £900 per annum and a pension of £400 per annum is allowed on certain conditions after 20 years' service. The sum of £100 will be allowed for passage expenses from Europe or America. The successful applicant is to begin his duties on March 1st, 1902. Further particulars may be obtained from the Agent-General for New South Wales, 9, Victoria-street, London, S.W., to whom applications, stating applicant's age (which must not be more than 40 years) and qualifications, and accompanied by four copies of each testimonial submitted, should be sent not later than Sept. 14th, 1901.

THE HOUSE OF LORDS AND THE EARLY CLOSING OF SHOPS.

THE report of the Select Committee of the House of Lords on the early closing of shops has just been issued. It is an instructive and important document though it can scarcely be said to convey any information of a novel character. Nevertheless its publication should be welcome as an effective reminder of a long-standing grievance for which reform is urgently needed. The Committee has satisfied itself that many shops still remain open from 80 to 90 hours a week; and even when the shops are closed there is still work to be done in packing goods, tidying, and making up the books. Eighty-four hours for a week of six days means 14 hours per day; and in 1888 the highest medical evidence was collected showing the injury of such long hours on the health, especially of young persons. On the present occasion this opinion has been repeated by the Presidents of the Royal College of Physicians of London and the Royal College of Surgeons of England respectively. Sir William Mac Cormac further urged that the evil increased with time and, he said, "it is gradual and progressive in its effects, and it goes on, I am afraid, in a cumulative degree." More than 290 petitions or resolutions passed by tradesmen's associations were received in favour of the Early Closing Bill; the London pawnbrokers alone objected. While acknowledging that the early closing associations had effected some good by voluntary action the evil, it was maintained, could only be eradicated by legislation. It is the inmates of the smaller shops who suffer most, and these tradesmen are quite as anxious to close earlier as are the more well-to-do shopkeepers. Nor is there any evidence that such action on their part would greatly inconvenience the poorer class of purchasers. The representatives of trade unions, of co-operative stores, &c., have all borne witness in favour of early closing. It is generally felt that voluntary action has done all that it is ever likely to accomplish and that legislation merely regulating the hours of labour of shop assistants will not be effective, for so long as the shops remain open the work will continue. The report concludes by saying that the evidence collected clearly shows that the present hours are "grievously injurious to health," therefore early closing "would be an immense boon to the shopkeeping community, to shopkeepers and shop assistants alike." Consequently the Select Committee recommends that town councils should be authorised to pass provisional orders for the closing of shops in their districts. These orders should be confirmed by Parliament in the usual manner so as to acquire the force of law. Thus so far as it goes this report is satisfactory, but what will be done? As far back as 1886 the House of Commons appointed a committee to inquire into the same subject, and it likewise reported that the long hours were injurious and often ruinous to health, yet, as we have seen, the grievance and the injury still continue. Will the evidence now collected by the House of Lords Committee produce any better fruit?

GLASGOW UNIVERSITY CLUB, LONDON.

THE summer dinner of the Glasgow University Club, London, was held at the Café Royal, Regent-street, W., on July 10th. Lord Balfour of Burleigh presided and the company, which reached a total of 95, included the Bishop of Ripon, the Earl of Mansfield, the Lord Provost of Glasgow, Sir Henry Craik, and Mr. J. A. Campbell, Member of Parliament for the Universities of Glasgow and Aberdeen. After the loyal toasts Lord Balfour of Burleigh proposed the toast of "The Club." Speaking on the subject of Mr. Carnegie's benefaction to the four Scottish universities he said that one of the objects of this great gift was to insure that no undue obstacle should be placed in the way of a liberal education being brought within the reach of those who were likely to profit by it. Mr. Carnegie had devoted for all time a sum of £100,000 a year for the benefit of these universities. The first charge on the fund, as finally constituted, was a definite sum of £50,000 a year for strengthening the departments which had hitherto been least supported—modern languages, modern literature, engineering, and other subjects of that kind. The first claim upon the remaining £50,000 would be the payment of the fees of such of the students as might apply for that benefit. There were some who looked with misgiving on this latter part of the scheme, believing that it was better that the fees of students should be paid by themselves or by their friends and that adventitious support was likely in the long run to be injurious; but Mr. Carnegie had met this difficulty by inserting a clause in the trust-deed which would enable students in after-life to repay to the trust the sums which they had received from it, so that there need be no sacrifice of their independence. No examination would be made into the circumstances of applicants, and Lord Balfour believed that this great gift would be fraught with excellent consequences for university life in Scotland. In concluding he highly commended the services rendered to the club by Mr. Norman MacLehose, who has just retired from the position of one of the secretaries. Sir Henry Craik proposed "The City of Glasgow" and Lord Provost Chisholm replied. The toast of "The Guests" was proposed by Mr. J. A. Campbell, M.P., and acknowledged by the Bishop of Ripon and the Earl of Mansfield. The bill of fare included haggis as one of the courses.

THE ARMY MEDICAL SERVICE.

IT would seem that the proceedings of the Committee of Inquiry instituted and presided over by Mr. Brodrick, the Secretary of State for War, are not intended to be of the wide and extended nature that was at first supposed, but are to be circumscribed within comparatively narrow limits. The committee will, it is understood, mainly confine their attention to the Army Medical Service and the Royal Army Medical Corps, with a view to find out what is required to be done to render them popular and efficient by bringing them into harmony with the requirements of the medical schools and the medical profession. It is not intended apparently that the organisation and state of army hospitals generally, or of those in South Africa in particular, should come within the scope of the investigation, although it is very likely that it may be found impossible to exclude these and other subjects from the inquiry. Mr. Brodrick has from the first expressed his intention of laying certain subjects and plans before a committee of experts for their consideration and advice, and it may well be that he seeks to put an end, once and for all, to future difficulties and dissensions by some bold, broad, and liberal scheme for creating the really good medical service which he has foreshadowed for the army of the future. The present Army Medical Service is organised on a purely military basis and it is possible, too, that with the aid of a number of civil hospital physicians and surgeons he may be seeking to devise a scheme by which scientific and professional attainments shall be more fully recognised in the army for reward in the future than they have been in the past, and that medical officers selected for the higher posts shall not only be good administrators but qualified to act as professional consultants in the districts and hospitals under their supervision. We shall see. Major-General Sir G de C. Morton, K.C.I.E., late Adjutant-General in India, Colonel Sir J. Willcocks, K.C.M.G., and Colonel Sir E. W. D. Ward have been added to the Committee. We still think that the Army Medical Service should have been more fully represented on the Committee, and the addition of the above three very able non-medical officers lends force to the protest to that effect which we have already raised. We trust, at all events, that some medical officer of experience with regard to administrative matters will have the opportunity of giving evidence if Mr. Brodrick does not see his way to make any further addition to the *personnel* of the Committee.

TEACHERS OF PUBLIC HEALTH IN LONDON AND THE CURRICULUM FOR THE DIPLOMA IN PUBLIC HEALTH.

AT a recently held meeting of teachers of public health in London the following resolution was passed with reference to the regulations laid down by the General Medical Council in December, 1900 :—

> That, in the opinion of this meeting of the teachers of public health in London, it is very desirable that a candidate for the diploma of Public Health should be required to attend a systematic course of three months' practical instruction in public health at a recognised school in lieu of three months' attendance with a medical officer of health. This course to run concurrently with those on bacteriology and chemistry. After this course the candidate should be required to attend day by day for three months with a medical officer of health and be associated with him in the discharge of his duties, routine and special, of public health administration.

The teachers consider that the regulations as laid down by the General Medical Council, even if they are not impracticable, will not produce as good results as would the scheme suggested by the teachers.

THE DRUNKARDS BILL.

So far as it goes the Drunkards Bill, which has now passed through the House of Lords, is calculated to prove distinctly beneficial as well to the inebriate himself as to the public. By its provisions the habitual drunkard convicted as such will be prohibited under penalties from purchasing intoxicating liquor on licensed premises for a term of three years. Licensees, on their part, will be liable if they knowingly sell, or permit the sale of, intoxicants to such a person. Of even greater importance from the social and domestic standpoint is the clause which allows the wife or husband of a habitual drunkard to obtain a separation order. Those who have been unfortunate enough to witness the misery and often hopeless ruin brought about in homes where the head is a drunkard will hail this clause as an earnest of domestic salvation. We would express a hope that in any case of separation under this Bill provision shall be made for such control of financial matters by responsible persons as shall insure the regular maintenance of those most nearly interested. The Bill further prohibits any person while drunk from taking charge of children under seven years of age. It provides that street drunkenness apart from disorder shall be treated as an indictable offence, and that publicans will be liable if they do not use their endeavours to prevent intoxication on licensed premises. It is to be hoped that in its progress through the House of Commons a measure which is now by no means oppressive will not from urgency of other business or from any other cause fail to receive that full consideration which it deserves.

THE PREVENTION OF CRUELTY TO CHILDREN.

The National Society for the Prevention of Cruelty to Children, as we learn from its latest annual report, has recently entered upon the thirteenth year of its existence. The last year's record is, on the whole, satisfactory. We may truly say that, except in so far as it still shows a certain, though not a great, excess of expenditure over income, it is a highly satisfactory record. The number of cases of cruelty inquired into was 2977 in excess of the number for the previous year. This fact at first sight does not suggest the most hopeful auguries. In reality it is not a sign of parental retrogression. It is rather to be taken as the latest high-water mark of the society's advancing and extending activity. Concurrently we learn that there has been a decrease in the number of reported cases of active ill-treatment, of exposure, of causing to beg, and of moral wrong. Still more encouraging is the statement, which is supported by the proof of recorded cases, that parents who formerly were cruel to their children have learned, even through the medium of punishment, the lesson of humanity. As the report rather quaintly puts it : "Something *better* in the experiences of the family has made the sacrifices of the new life worth while." In other cases a knowledge of the society's interest in children has acted as a deterrent upon callous and neglectful parents. Reformation of character is, as we have repeatedly stated, as much a primary object of the society's efforts as is the prevention of cruelty. It aims at so administering the powers intrusted to it by law that judicious common-sense will find its due exercise as well as the sometimes indispensable machinery of punishment. Here and there in the report complaint is made that local magistrates do not sufficiently avail themselves of the powers of correction intrusted to them but prefer to adopt a let-alone policy even where there is evidence of serious misdemeanour. In one case of culpable and fatal neglect a conviction was obtained on appeal to a higher court and the offending parent was severely punished. In other cases justices have shown themselves, fully alive to the curative value of preventive legislation and have done all in their power to promote its objects. These evidences of divergence in legal opinion can only be the result of misunderstanding which a better acquaintance with the aims of the society and the unfortunate condition of social life in many families will go far to rem
A suggestion contained in the report contemplates creation of a State Department which shall devote energies to the protection of children's interests. We m confess that this proposal does not commend itself to judgment. The State has already done much by framin series of useful Acts all bearing upon this subject, and b doing it has furnished the public with every reasonable me of redress. A national society exists which has pro itself abundantly capable of performing the duties of authorised and disinterested protector. With these visions in being and in operation we fail to see any adequ justification for a new arrangement which must inevita

be relatively perfunctory in its character, unsympathetic, mechanical—in a word, official We would rather leave well alone, and having powers of law employ these with the aid of self-help inspired by humanity and good sense.

THE CHEMISTRY OF ARTIFICIAL FLOWERS.

MANY persons have been rudely shocked to find that a flower for which perhaps they gave a considerable sum and which they took to be genuine proved subsequently to be artificial in every particular Within our own experience not long ago the attention of a gentleman sitting at dinner was drawn to the fact that his shirt-front and coat were gradually being covered with streaks of a brilliant red colour. He was wearing a bright carnation in his button-hole which at quite a short distance, as it subsequently appeared, deceived perfectly. Even the perfume was admired. The "flower" had just been watered to freshen it and it was then seen that on the water-drops detaching themselves they were of a brilliant red colour while the "carnation" gradually assumed a faint variegated appearance owing to some of the colouring matter being washed out General incredulity was expressed that, at first sight, the flower could be anything but real. A laboratory examination, however, soon brought the whole truth to light, and the results are remarkable and certainly a credit to the ingenuity of the designer. There was not the vestige of a carnation about it. The "flower" consisted of slices of turnip neatly cut and dyed with acid magenta; the stems and leaves were of twisted cloth dyed a dark green with chromium; the bloom was a very fine starch powder delicately dusted over the stems and leaves; and the support to the whole clever fabric was a concealed iron wire A synthetic amber-coloured oil known as "*œillet*" completed the deception in giving a perfume wonderfully imitative of the genuine carnation. Altogether we can hardly conceive of a cleverer deceit and it is satisfactory to be able to add that so far as our observations went it is free from positive harm except to wearing apparel. On carefully searching the various materials for irritating substances and poisonous metals we could not obtain the slightest evidence that such were present. It is clearly possible, however, that the colours used for artificial flowers may contain substances injurious to health—such as, for example, arsenic.

THE QUANTITY OF WATER IN FOODS.

IT is not very generally realised how much water there is in solid food. Certain it is that no natural food is without water, varying in amount from 5 to 97 per cent., or only 3 per cent. short of pure water itself. Milk, of course, must be taken as the type of a complete food and yet it contains, even straight from the cow, very nearly 90 per cent. of water, or, to be more accurate, from 87 to 88 per cent. That is to say, more than four-fifths of milk consist of water, and as this is the condition in which it is naturally furnished the inference is that the fats, the sugars, and the proteids were intended to be taken in a diluted state. Indeed, the composition of other foods would teach the same thing, although, paradoxical as it may seem, some solid foods contain more water than does milk. This is especially true of vegetables and fruits. Thus the turnip contains over 90 per cent. of water, the cabbage nearly the same amount, and the cucumber and the vegetable marrow about 95 per cent.; whilst amongst fruits the strawberry contains nearly 90 per cent. of water, the apple 82 per cent., and grapes 80 per cent. Even the various meats used as food contain an amount of water far in excess of the amount of solid constituents. Thus three-fourths of beef and mutton consist of water. The housekeeper, perhaps, scarcely realises when consulting the butcher's price-list that three-fourths of the meat are water and are paid for with the rest at the rate of a shilling or more per pound. Lamb contains less water, namely 64 per cent., pork still less, 60·9 per cent, and bacon only 22·3 per cent. It would appear that as the flesh foods increase in the amount of fat the proportion of water, as a rule, diminishes. Coming to birds, the flesh of the fowl and duck contains about 70 per cent. of water and that of the pigeon 75 per cent., while the flesh of the goose contains only 38 per cent., the last being another example of the fat increasing with a corresponding diminution in the proportion of water. Fishes contain from 40 to 80 per cent. of water. The egg, one of the most powerful of nutritives, contains 65 5 per cent. of water, the white consisting of 86 per cent and the yelk of 50·9 per cent The latter, of course, is the more nourishing part. As a rule foods containing a small proportion of water are not fit for human consumption until they are cooked, which commonly means reducing them to a digestible state by adding water and boiling or baking, and so when they are actually partaken of they contain a good percentage of water Wheat flour, for example, contains only 12 per cent. of water, while bread contains nearly 50 per cent. It would appear to be necessary, therefore, that food should be in a decidedly moist condition before it is fit for use, and thus water plays a rôle in food which at first sight perhaps does not seem evident. Bacteria cannot live or act except under a wet environment and chemical change under absolutely dry conditions is impossible; therefore without moisture life would cease and the great vital processes would come to an end.

THE PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MR. HENRY GREENWAY HOWSE was on July 11th elected President of the Royal College of Surgeons of England. Mr. Howse was a student of Guy's Hospital, whence he qualified with the Membership of the Royal College of Surgeons of England in 1865 He obtained the M.B. of London in the following year, and the Fellowship of the Royal College of Surgeons of England and the M.S. of the University of London in 1868. Mr. Howse has been a member of the surgical staff of Guy's Hospital for many years and he is now the senior surgeon and the lecturer on surgery. He has contributed numerous papers on various surgical subjects to Guy's Hospital reports, to the Transactions of the societies, and to the medical journals. We offer him our congratulations on the honour conferred upon him.

THE DISTRIBUTION OF PLAGUE.

A TELEGRAM received at the Colonial Office from the Governor of Mauritius on July 12th states that for the week ending July 11th two fatal cases of plague had occurred. At Hong-Kong for the week ending July 13th there had been 26 cases of plague with 21 deaths. With regard to the plague cases in the lazaretto at Frioul our Paris correspondent writes: "The daily press has been making a great fuss about seven cases of plague which have occurred on board the transport Laos among the Arabs whom the ship had embarked at Djibouti on her return from Cochin The matter is of but little importance. In all 15 cases occurred among the Arabs, one case being landed at Port Said. On arrival at Marseilles the ship was isolated at Frioul, the passengers were placed in quarantine, and the Arabs put on board a hulk which was also isolated. There were three deaths. All the passengers and the medical staff attending them were inoculated with Calmette's serum The Arabs at first refused inoculation and only consented after the death of one of their number. No new case has occurred and the passengers and returned troops are shortly to be allowed to go free. There is no other centre of infection in Marseilles, all infection being confined to Frioul, and despite the great heat the death-rate is no higher than is usual at this time of the year. The incident affords proof of how carefully organised is the Marseilles Sanitary Department and what good security it offers against Europe being invaded by plague through that port." During the week ending July 7th fourteen cases of plague and seven deaths from the disease have been notified throughout all Egypt. Nine of these cases and six deaths have occurred at Zagazig, three cases and one death at Alexandria, and two cases at Port Said. Eleven of the cases occurred among natives and three among Europeans (all Greeks). A Greek youth, aged 18 years, employed in a baker's shop in the European quarter of Port Said, was admitted into hospital on July 4th with typical symptoms of plague. Dr. Baker, the sanitary inspector, examined the inmates of the surrounding houses, and found in the next house, occupied as a grocer's shop, a Greek boy, aged 13 years, suffering from similar symptoms. This boy also was immediately isolated and the whole quarter was thoroughly disinfected.

THE Council of the Royal Society has awarded the Mackinnon Studentship to Mr. J. J. R. Macleod, M.B. Aberd., Demonstrator of Physiology in the London Hospital Medical College, for the purpose of enabling him to carry out researches in pathological chemistry. The studentship is founded under a bequest to the Royal Society by the late Sir William Mackinnon, Director-General of the Medical Department of the Army, for the foundation and endowment of prizes or scholarships for the special purpose of furthering natural and physical science, and of furthering original research and investigation in pathology. The studentship is of the annual value of £150. There were 14 applications for the studentship.

THE King held an Investiture at Marlborough House on July 16th, when the honour of Knight Commander of the Royal Victorian Order was conferred upon the following gentlemen:—Sir Thomas Smith, Bart., F.R C.S. Eng. ; Deputy Surgeon-General Henry Julius Blanc ; and Mr. William Henry Bennett, F.R.C.S. Eng. The following gentlemen were invested with the Insignia of Commanders of the Order:—Mr. Donald William Charles Hood, M.D. Cantab. ; Mr. John Hammond Morgan, F.R.C.S. Eng., and Mr. Charles Arthur Morris, F.R.C.S. Eng.

WE are sure that we are only giving expression to the feeling of the whole of the medical profession in offering our sympathy to Sir Richard Douglas Powell in the sorrow which has fallen upon him by the death of his son, Lieutenant Charles Folliott Borradaile Powell of the Mounted Infantry, Yorkshire Light Infantry, who was killed at Rietfontein on July 13th. Lieutenant Charles Powell was the second son of his father; his elder brother, of the Royal Welsh Fusiliers, is now serving in South Africa.

IN regard to the case of Stocks and Crossman *v.* Watson, upon which we commented in a leading article published in our issue of July 13th (p. 91), we think it right to say that the interests of the medical men who were successful on the claim and counter-claim in this action were looked after by the British Medical Protection Society.

THE new Dental Hospital of London, Leicester-square, has received a legacy of £1000 under the will of the late Miss Hannah Harvie of Cheltenham.

THE BRITISH CONGRESS ON TUBERCULOSIS.

THE British Congress on Tuberculosis will be opened on Monday, July 22nd. It will be inaugurated by the president, the Duke of Cambridge, on behalf of the King, who is patron of the Congress and who is deeply interested in its work. The headquarters of the Congress are at the Queen's Hall, Langham-place, W., but the opening meeting will take place in St. James's Hall, Piccadilly, at 3 P.M. on July 22nd, and two other general meetings will be held at the same place and hour on July 23rd and 24th. On July 25th a fourth general meeting will be held in the Queen's Hall, where on the following day the Congress will be closed by a final general meeting. There are to be four sections of the Congress. Section I. will be the State and Municipal section, and will meet daily at St. George's Hall, Langham-place, W. ; Section II. is to deal with Medicine, including Climatology, and its meetings will be held in the large hall of the Royal Medical and Chirurgical Society, 20, Hanover-square, W.; Section III., for Pathology, including Bacteriology, will meet at the Queen's Hall; and Section IV., the Veterinary section, will hold its meetings in the Marlborough Hall, adjoining the Polytechnic, Regent-street, W. In each case the meetings will last from 9.30 A.M. to 1.30 P.M. There will be a museum in connexion with the Congress, and this will be located at the Queen's Hall and will be open daily.

The Congress will consist of honorary members, delegates, and members. Honorary members will be persons nominated by any foreign Government or university, or by the executive committee; delegated and ordinary members will be other persons, British, colonial, or foreign, who may wish to attend, including representatives from Governments or institutions within the British Empire. Delegated and ordinary members will receive their cards on forwarding the sum of £1 to the secretary-general of the Congress, 20, Hanover-square, W. Arrangements have been made with all the principal railway companies in Great Britain to issue tickets to the members of the Congress at a fare and a quarter for the return journey, available from July 20th to July 29th inclusive. These tickets are obtainable from the booking clerks at all important railway-stations on production of a certificate signed by the secretary of the reception committee which will be posted at the same time as the Congress ticket to all those who subscribe and enrol themselves as members. The Queen's Hall, Langham-place, will be open as a general reception-room and central bureau for the registration of delegates and members, the distribution of Congress tickets, and for the reception of applications for special entertainments. The reception-room will be open on Saturday, July 20th, from 10 A.M. to 1 P.M., for registration of names and distribution of tickets. It will also be open between these hours on Sunday, July 21st, for the convenience of members from a distance. On Monday, July 22nd, the Queen's Hall will be open from 9.30 A.M. to 5 P.M. for registration and distribution of tickets and from 9 P.M. to midnight there will be a reception here by the president of the council and the executive officers of the Congress.

On Tuesday, July 23rd, the sections will begin their work, and at the second general meeting on the afternoon of this day Professor R. Koch of Berlin will give an address. The chair will be taken by Lord Lister. From 9 o'clock to 12 on the same evening the Lord Mayor and Lady Mayoress will hold a reception at the Mansion House. On Wednesday, July 24th, there will be in the morning, at 20, Hanover-square, a joint meeting of the Sections of Medicine and Pathology for a discussion on Tuberculin. Professor Brouardel of Paris will address the third general meeting in the afternoon. At this meeting Mr. Henry Chaplin, M.P., will be the chairman. From 4.30 to 7 P.M. a garden party will be given by the ladies' reception committee in the Royal Botanic Gardens, Regent's Park. The fourth general meeting, to be held on Thursday, July 25th, will be addressed by Professor McFadyean, of the Royal Veterinary College, and Lord Spencer will preside. From 4.30 to 5 30 P.M. the council of the Sanitary Institute will hold a reception at the Parkes Museum of Hygiene, and from 9.30 P.M. to 12 a reception will be given by the Earl and Countess of Derby at the Victoria and Albert Museum. On Friday, July 26th, Lord Derby will preside at the final meeting of the Congress. Sir J. Whittaker Ellis will give a river party at Richmond on the same afternoon, and in the evening the foreign vice-presidents and foreign delegates will be entertained at dinner at the Hotel Cecil On Saturday, July 27th, from 4 to 7 P M., the Duke and Duchess of Northumberland will give a garden party at Syon House

The papers to be read at the Congress will practically cover the whole field of the subject of tuberculosis In Section I "The Statistical Aspect of Tuberculosis" will be considered first Then will follow "The Notification of Tuberculosis," "The Prevention of Tuberculosis during Childhood," "The Influence of Housing and Aggregation," "The Control of Meat Supplies," "The International Aspects of Tuberculosis," "The Control of Milk-supplies," "The Provision of Sanatoria," and "The Rôle of Hospitals and Dispensaries for Consumption in the Prevention of Phthisis" In Section II there will be a discussion on the question, "What Influence has Climate on the Treatment of Consumption, and how far can cases be grouped for Treatment in Certain Climates?" This will be followed by discussions on "The Therapeutic and Diagnostic Value of Tuberculin in Human Tuberculosis," and "Sanatoria for Consumption" Section III will consider "The Morphological and Physiological Variations of the Bacillus Tuberculosis and its Relations (*a*) to other acid-proof Bacilli, (*b*) to the Ray Fungus and other Streptothrices;" "The Varieties of Tuberculosis (Morbid Anatomy and Histology)," and "Mixed Infection in Tuberculosis" Section IV will discuss "The Diagnosis of Tuberculosis in Animals during Life," "Tuberculosis and the Milk Supply," "Tuberculosis and the Meat Supply," and "The Legislative and other Measures necessary to combat Tuberculosis amongst Animals" A large number of papers dealing with these questions will be read by recognised authorities

The following are the principal officers of the Congress President of Organising Council, the Earl of Derby, Chairman of Organising Council, Sir William Broadbent, F R.S ; Chairman of General Purposes Committee, Professor Clifford Allbutt, F R.S ; Chairman of Reception Committee, Sir James Crichton Browne, F R.S ; Chairman of Finance Committee, Sir James Blyth , Hon Treasurers, Lord Avebury and Sir James Blyth ; Hon. Secretary-General, Mr Malcolm Morris ; President of Ladies' Reception Committee, the Countess of Derby ; Hon Foreign Secretary, Dr StClair Thomson , Hon Secretary of Reception Committee, Dr Alfred Hillier ; Hon Secretary of Museum Committee, Dr W Jobson Horne ; Hon Secretary of Architectural Section of Museum, Mr Thomas W Cutler ; Hon Assistant-Secretary, Sir Arthur Trendell, C M G The following are the presidents of sections Section I, Sir Herbert Maxwell, M P , F R.S ; Section II , Sir R. Douglas Powell , Section III , Professor Sims Woodhead, F R.S Edin , Section IV , Sir George Brown C B

COMPLIMENTARY DINNER TO SURGEON-GENERAL JAMESON, C B

MR. G LENTHAL CHEATLE one of the honorary secretaries, has sent us the following list of names to be added to those which we published in our issue of July 6th, 1901, as those of members of the medical profession and others who wish to do honour to the late Director General of the Army Medical Service —Sir George Philipson, Surgeon-General A F, Preston, Surgeon General J B C Reade, C B , Surgeon-General Martin Surgeon General A C C De Renzy, C B , Dr H H Tooth C M G , Dr Conan Doyle, Dr Dudley Buxton, Mr Woodhouse Braine, Mr Thomas Wakley, jun , and Dr H Tilley The dinner will be held at the Hotel Cecil on Wednesday July 24th

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN 33 of the largest English towns 6483 births and 3439 deaths were registered during the week ending July 13th The annual rate of mortality in these towns, which had been 14·8 and 15·1 per 1000 in the two preceding weeks, further rose to 15·6 per 1000 last week. In London the death-rate was 14·2, while it averaged 16·6 in the 32 large provincial towns The lowest death rates in these towns were 9·4 in Halifax, 10·1 in Croydon and in Plymouth, 10·3 in Derby, and 10·6 in Bristol , the highest rates were 20·0 in Portsmouth, 21·2 in Preston, 25·9 in Liverpool, and 26·7 in Birkenhead The 3439 deaths in these towns last week included 567 which were referred to the principal zymotic diseases, against 399 and 431 in the two preceding weeks , of these, 297 resulted from diarrhœal diseases, 95 from measles, 63 from diphtheria, 53 from whooping cough, 41 from scarlet fever, 16 from "fever" (principally enteric), and one from small-pox. No death from any of these diseases was registered last week in Brighton or in Halifax ; in the other towns they caused the lowest death rates in Croydon, Norwich, and Huddersfield, and the highest rates in Portsmouth, Sheffield, Liverpool, and Birkenhead The greatest mortality from measles occurred in Gateshead and Birkenhead , from whooping cough in Swansea and Bradford , and from diarrhœal diseases in Leeds, Portsmouth, Sheffield, Liverpool, and Birkenhead The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns The 63 deaths from diphtheria in the 33 towns included 24 in London, six in Liverpool, five in Manchester, four in Leicester, and four in Leeds One fatal case of small-pox was registered in Liverpool, but not one in any of the other 32 towns , six small-pox patients were admitted into the Metropolitan Asylums hospitals during the week, and 12 remained under treatment on Saturday, July 13th The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2918, against numbers increasing from 1522 to 2895 on the 11 preceding Saturdays , 324 new cases were admitted during the week, against 369, 408, and 363 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 141 and 165 in the two preceding weeks, fell again last week to 133, and were 44 below the corrected average The causes of 20, or 0·6 per cent , of the deaths in the 33 towns were not certified, either by a registered medical practitioner or by a coroner All the causes of death were duly certified in West Ham, Bristol, Leeds, Sheffield, Nottingham, Bradford, and in 15 other smaller towns , the largest proportions of uncertified deaths were registered in Liverpool and in Portsmouth

HEALTH OF SCOTCH TOWNS

The annual rate of mortality in the eight Scotch towns, which had been 17·3 and 19·0 per 1000 in the two preceding weeks, fell again to 17·2 per 1000 during the week ending July 13th, and showed an excess of 1·6 per 1000 over the mean rate during the same period in the 33 large English towns The rates in the eight Scotch towns ranged from 11·5 in Aberdeen and 12·7 in Leith to 23·6 in Greenock and 24·2 in Dundee The 549 deaths in these towns included 29 which were referred to diarrhœa, 22 to measles, 22 to whooping-cough, seven to scarlet fever, six to "fever," two to diphtheria, and one to small pox. In all, 89 deaths resulted from these principal zymotic diseases last week, against 86 and 81 in the two preceding weeks These 89 deaths were equal to an annual rate of 2·8 per 1000, which was 0·2 per 1000 above the zymotic death rate last week in the 33 large English towns The fatal cases of measles, which had been 25 in each of the three preceding weeks, declined last week to 22, and included 14 in [illegible] and six in Edinburgh The deaths from diarrhœa, which had been 13 24, and 19 in the three preceding weeks, rose to 29 last week, and included 15 in Glasgow, five in Dundee, and three in Edinburgh The deaths from scarlet fever, which had been seven in the two preceding weeks, were last week again seven, of which five occurred in Glasgow, where the two deaths from diphtheria and the one death from small pox were registered The six deaths from fever last week showed an increase of five, and included two in Glasgow The deaths referred to diseases of the respiratory organs in these towns which had been 95 in each of the two preceding weeks, fell last week to 75, and showed an excess of four over the number in the corresponding period of last year The causes of

HEALTH OF DUBLIN

The annual rate of mortality in Dublin, which had been 18 2 and 20 7 per 1000 in the two preceding weeks, further rose to 21 0 during the week ending July 13th During the past four weeks the death rate has averaged 20 0 per 1000, the rates during the same period being 14 1 in London and 16 9 in Edinburgh. The 151 deaths of persons belonging to Dublin registered during the week under notice were two more than the number in the preceding week, and included 10 which were referred to the principal zymotic diseases, against five and seven in the two preceding weeks; of these four resulted from whooping-cough, four from diarrhœa one from scarlet fever, and one from diphtheria These 10 deaths were equal to an annual rate of 1 4 per 1000, the zymotic death rate during the same period being 1 9 in London and 1 8 in Edinburgh The deaths from whooping-cough and from diarrhœa showed an excess over the numbers recorded in recent weeks The 151 deaths in Dublin last week included 26 of infants under one year of age and 32 of persons aged upwards of 60 years, the deaths of infants showed an increase, and those of elderly persons a decline from the numbers in recent weeks Three inquest cases and two deaths from violence were registered, and 53, or more than one-third, of the deaths occurred in public institutions The causes of eight, or more than 5 per cent, of the deaths in Dublin last week were not certified.

VITAL STATISTICS OF LONDON DURING JUNE, 1901

T[illegible] table will be found summarised [illegible] to sickness and mortality in each [illegible]oughs in the county of London With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 8 5 per 1000 of the population, provisionally estimated at 4 543,757 persons in the middle of the year In the three preceding months the rates had been 5 3, 5·2, and 8 5 per 1000 respectively The rates were considerably below the average in Chelsea, Kensington, the City of Westminster, Hampstead, Stoke Newington, and Wandsworth, while they showed the largest excess in Hackney, Finsbury, Shoreditch, Bethnal Green, Southwark, and Bermondsey Four cases of small pox were notified in London last month; of these, one belonged to St Marylebone, one to St. Pancras, one to Hackney and one to Stepney Five small-pox patients were admitted into the Metropolitan Asylums during the month, and five remained under treatment on Saturday, June 29th The prevalence of scarlet fever was slightly less excessive than in the preceding month, among the various metropolitan boroughs this disease was proportionally most prevalent in the City of London, Shoreditch, Bethnal Green, Southwark, and Bermondsey The Metropolitan Asylums Hospitals contained 2752 scarlet fever patients at the end of June, against 1533, 1491, and 2291 at the end of the three preceding months, the weekly admissions averaged 343, against 142, 179, and 339 in the three preceding months The prevalence of diphtheria showed a further increase upon that recorded in any recent month, the greatest proportional prevalence of this disease occurred in St. Pancras, Hackney, Finsbury, Bethnal Green, Stepney, Poplar, and Camberwell boroughs. There were 1169 diphtheria patients under treatment in the Metropolitan Asylums Hospitals at the end of June against 1084, 960, and 1101 at the end of the three preceding months, the weekly admissions averaged 175, against 134, 117, and 160 in the three preceding months Enteric fever was slightly more prevalent than in the preceding month, among the various metropolitan boroughs the greatest proportional prevalence of this disease occurred in Paddington, Hammersmith, Shoreditch, Bethnal Green, and Poplar The number of enteric fever patients under treatment in the Metropolitan Asylums Hospitals, which had been 162, 121, and 95 at the end of the three [illegible] to 125 at the end of June, [illegible] last month, against 18, 16, [illegible]nths Erysipelas was proportionally most prevalent in St. Marylebone, St Pancras, Finsbury, Bethnal Green Bermondsey, and Greenwich The 12 notified cases of puerperal fever included three in Woolwich and two in Islington.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various metropolitan boroughs, the deaths occurring in the public institutions of London having been distributed among the various boroughs in which the deceased persons had previously resided During the four weeks ending June 29th the deaths of 4662 persons were registered, equal to an annual rate of 13 4 per 1000, against 18 2, 17·6, and 15 4 per 1000 in the three preceding months The lowest death-rates last month in the various metropolitan boroughs were 8 1 in Stoke Newington, 8·9 in Hampstead, 10 4 in Battersea and in Lewisham, 10 5 in Woolwich, and 10 7 in Paddington and in Wandsworth, the highest rates were 16 9 in Stepney, 17 3 in Shoreditch, 17 5 in Finsbury, 17 6 in Holborn, 18 2 in Southwark, and 19 1 in the City of London During the four weeks of June 516 deaths were referred to the principal zymotic diseases, of these one resulted from small pox, 165 from measles, 63 from scarlet fever, 64 from diphtheria, 116 from whooping-cough, one from typhus, 16 from enteric fever, 90 from diarrhœal diseases, and not one from any ill defined form of continued fever The lowest death-rates last month from these diseases occurred in Paddington, Kensington, Hampstead, Lewisham, and Woolwich, and the highest rates in Shoreditch, Stepney, Poplar, Southwark, Bermondsey and Greenwich The fatal case of small-pox was that of a person belonging to St Marylebone The 165 deaths from measles showed a marked decline from the average number in the corresponding periods of the 10 preceding years, this disease was proportionally most fatal in Holborn, Stepney, Poplar, Southwark, Bermondsey, and Greenwich The 63 fatal cases of scarlet fever nearly corresponded with the corrected average number, among the various metropolitan boroughs the greatest proportional mortality from this disease occurred in Finsbury, Shoreditch, Stepney, Southwark, Bermondsey, and Deptford The 64 deaths from diphtheria showed a decline of 84 from the average number in the corresponding periods of the 10 preceding years, this disease showed the highest proportional fatality in Hammersmith, St Pancras, Bethnal Green, Bermondsey, and Woolwich The 116 fatal cases of whooping cough showed a considerable decline from the corrected average number, among the various metropolitan boroughs this disease was proportionally most fatal in Hammersmith, Fulham, Holborn Poplar, and Greenwich The 17 deaths from "fever" were about one half the average number in the corresponding periods of the 10 preceding years; the highest "fever" death rates occurred in Stoke Newington, Shoreditch, Bethnal Green, Southwark, and Deptford The 90 deaths from diarrhœal diseases were 70 less than the corrected average number, among the various metropolitan boroughs the proportional mortality from this cause was highest in St Pancras, Stoke Newington, Shoreditch, Stepney, and Poplar In conclusion, it may be stated that the aggregate mortality from these principal zymotic diseases in London during June was nearly 39 per cent below the average Infant mortality in London last month, measured by the proportion of deaths of children under one year of age to registered births, was equal to 103 per 1000 The lowest rates of infant mortality were recorded in Kensington, Chelsea, St Marylebone, Hampstead, and Stoke Newington, and the highest rates in Hammersmith, St Pancras, Holborn, Shoreditch, Southwark, and Wandsworth

THE SERVICES

ROYAL NAVY MEDICAL SERVICE

THE following appointments are notified —Staff Surgeon J Andrews to the *Fox*, on commissioning for the manœuvres

ROYAL ARMY MEDICAL CORPS

Lieutenant Steele is placed under orders for South Africa Major G H Barefoot has assumed command of the Depot at Aldershot. Surgeon Lieutenant T G McAllum, M M S C, and Lieutenant S F Briggs, M M S C, are attached to the Cambridge Hospital Aldershot, for duty Lieutenant Colonel A Young (r p) is selected for employment at Perth. Lieutenant O R Evans holds himself in readiness to embark for India. Surgeon-Lieutenant J R Bibby, 1st Gloucestershire Volunteer Artillery, has joined at Aldershot for a month's course of instruction Major Patrick Maurice Carleton retires on retired pay Dated July 19th, 1901 Lieutenant

James Barkley resigns his commission. Dated July 17th, 1901. Civil Surgeon Ernest George Ffrench to be Lieutenant. Dated May 28th, 1901. Lieutenant-Colonel R. W. Barnes (retired) is granted the local rank of Colonel while in charge of a general hospital in South Africa. Dated June 8th, 1900.

VOLUNTEER CORPS.

Rifle: 2nd (Renfrewshire) Volunteer Battalion Princess Louise's (Argyll and Sutherland Highlanders): Surgeon-Lieutenant-Colonel M. H. Taylor resigns his commission, with permission to retain his rank and to wear the uniform of the battalion on retirement. Dated July 13th, 1901. 2nd Volunteer Battalion the Queen's Own (Royal West Kent Regiment): James Hamilton to be Surgeon-Lieutenant. Dated July 13th, 1901.

VOLUNTEER MEDICAL STAFF CORPS.

The Glasgow Companies:—Francis James Charteris to be Surgeon-Lieutenant. Dated July 13th, 1901. John Thomson Kilpatrick Thomson to be Surgeon-Lieutenant The Woolwich Companies: Surgeon-Captain C. H. Hartt to be Surgeon-Major. Dated July 13th, 1901.

VITAL STATISTICS OF THE DUTCH NAVY FOR THE YEAR 1899.

Home stations:—Average strength, 4418; admissions to hospital, 1019 per 1000, including 221 per 1000 on account of venereal and skin affections; death-rate, 2·5 per 1000. East Indian possessions:—Europeans: strength, 2365; admissions, 1748 per 1000, including 583 per 1000 on account of endemic diseases (chiefly paludal), and 350 per 1000 on account of venereal affections; death-rate, 7·1 per 1000. Natives: strength, 920; admissions, 1180 per 1000; death-rate, 9·7 per 1000. Various foreign stations:—Strength, 1652; admissions, 1220 per 1000; death-rate, 1·2 per 1000. The mortality on home service seems very low, but the above figures do not represent the whole of it. In the following towns—Willemsoord, Amsterdam, Helvoetsluis, Rotterdam, Leyden, and Flushing—there are hospitals to which the wives and children of men belonging to the navy are admitted as well as the husbands and fathers, and apparently the statistics referring to the latter are excluded from the general table. The number of patients (men, women, and children) treated in these establishments during the year was 4523, and amongst them there were 55 deaths. In addition to statistics the report contains a variety of miscellaneous information. At Leyden the medical officer in charge vaccinated eight children aged respectively from seven months to three and a half years. It is customary in the Netherlands to insert the lymph in 10 separate places, and in the present instance the whole 80 punctures were attended by well-developed pustules. The same officer revaccinated 258 adults, but as in revaccination only five punctures are usual the total number of these was 1290. The results were certainly remarkable, 43 per cent. of the punctures were followed by pustules which are said to have been characteristic. In about 25 per cent. of the cases, however, lymphangitis and adenitis likewise supervened, while in 5·4 per cent. more there was "peri-vaccinal erythema." In an interesting appendix Dr. van Dewenter gives an account of his anthropometric investigation of 283 naval cadets, aged from 13½ years to 16½ years. It would seem to be one of the sequelæ of the training which these young men undergo that they should fail to become long-headed! Each year their crania increase about two centimetres in circumference, but it is "the transversal diameter which augments rather than the frontal." Dr. van Dewenter's communication is plentifully illustrated by diagrams and tables.

AFFAIRS IN SOUTH AFRICA.

There is, we regret to say, a good deal of sickness at the front, in addition to the casualties that occurred at Vlakfontein, about which and the alleged murder of some our wounded so much stir has arisen. The list of those rously ill, and mainly from that army scourge enteric a long one. The death-rate among the Boer women en in the concentration camps was a lamentably t an improvement, has, we are glad to say, taken espect. The sickness and suffering which war ls upon the powerless and innocent are indeed Mr. Kruger and his advisers should surely ll that before thrusting war upon this e official publication of papers relating to n Lord Kitchener and Commandant- strong side-lights thrown upon them by the papers captured by Sir Bindon Blood, the statements in Parliament, and the appearance of Mr. E. T. Cook's book on the "Rights and Wrongs of the Transvaal War," there should be no lack of evidence and material on which to form an opinion about it. We know now about as much as is to be known as to the causes which led to it, the preparations which were made for its occurrence by the Boer Government, and the determination on the part of Mr. Kruger and the hostile commanders to continue it until their terms, and not those of this country, are granted. They really abate no jot of the demands which they made when they delivered their ultimatum and followed it up by invading our territories at the beginning of the war in 1899. That is really, when summarily and dispassionately stated, the present position of affairs, and it seems to cut the ground from beneath the feet of those who are advocating a policy of conciliation, the fact being that Mr. Kruger and the Boers, so far from regarding themselves as beaten, proclaim that they are as hopeful of success and as determined on maintaining their independence as ever they were. We have learned one thing, at any rate, in the present case—that the capture and annexation of territories and their capitals are not tantamount to the submission and subjection of the population: they are by no means conterminous results. Where the irreducible minimum which a foe will accept is what in the opinion of the other side is not even an admissible subject in any discussion about terms there is obviously only one course open—namely, to go on with the fighting—and this, in the opinion of most people in this country and the colonies, will have to be done if the integrity of the British Empire is to be maintained. The Boers are losing every week men, horses, rifles, and ammunition which cannot be replaced and the process, if slow, is still one of steady disintegration of their forces. As regards their attacks on trains it has been shrewdly suggested that a batch of Boer prisoners should in future be put in the foremost trucks or carriages of every train, and as regards the relief and aid of families in concentration camps there were both common-sense and humour in the inquiry of someone in the body of a meeting whether Mr. Kruger, who held the money-bags, had been asked to subscribe. According to the last detailed statement of British casualties published by the War Office there have been 16,717 deaths since the beginning of the war up to the end of last month, and the actual reduction of the force through the war from all causes amounts to 20,418.

DEATHS IN THE SERVICES.

Inspector-General of Hospitals and Fleets Thomas Henry Knott, R.N., on July 5th, aged 59 years. He entered the Navy in 1867, was promoted to Staff Surgeon in 1872, to Fleet Surgeon in 1883, to Deputy Inspector-General in 1892, and to Inspector-General in 1898.

Deputy Inspector-General Thomas Beswick Purchas, R.N. (retired), on July 6th, aged 76 years. He entered the Navy in 1847 as assistant surgeon to Her Majesty's ship *President*, stationed at Cape Town. In 1857 he became Staff Surgeon, previously to which he was Surgeon to the *Flying Fish*, one of the squadron that accompanied His Royal Highness the Prince of Wales on his visit to Canada. In 1863, when stationed at Japan, he took part in the action off Nagasaki. In 1869 he was promoted to Fleet Surgeon. He retired in 1876 with the rank of Deputy Inspector-General. The deceased gentleman was a prominent Freemason and served the office of Past Assistant Grand Director of Ceremonies and was P.Z. and P.A.G.Soj. in the Royal Arch degree.

Deputy Inspector-General Richard Domenichetti on July 12th, at his residence, Woodhall Spa, aged 78 years. An obituary notice will be found in another column.

On July 17th the King presented medals of the Grand Priory of the Order of the Hospital of St. John of Jerusalem in England for conspicuous services to the Ambulance Department. The recipients were: Sir John Furley, Chief Commissioner of the Central British Red Cross Committee, Hon. Bailiff; Mr. William Henry Morgan, Hon. Associate of the Order, chief superintendent of the Metropolitan Corps, St. John Ambulance Brigade; Mr. Richard Berdett-Sellers, Hon. Associate of the Order, M.R.C.S. Eng., chief surgeon, Rochdale Corps, St. John Ambulance Brigade; Mr. Marshall Hopper, Hon. Serving Brother of the Order, chief superintendent of the Hull Corps, St. John Ambulance Brigade; Mrs. Priscilla Laverack, Hon. Serving Sister of the Order, Hull Nursing Division, St. John Ambulance Brigade; Mr.

Robert Slater, private, Hull Corps, St. John Ambulance Brigade; Dr. Charles Henry Milburn, Esquire of the Order, Deputy Commissioner No. 6 District, St. John Ambulance Brigade; Dr. George Thomson, Hon. Associate of the Order, chief surgeon, Oldham Corps, St. John Ambulance Brigade; and Mr. Benjamin Sellars, first officer, Oldham Corps, St. John Ambulance Brigade.

Correspondence.

"Audi alteram partem."

"UNBOILED v. BOILED MILK."

To the Editors of THE LANCET.

SIRS,—In the letters which have been addressed to you on this subject I have been struck by the absence of any reference to experimental data. Yet there is a large amount of experimental evidence bearing directly upon the points at issue. May I ask for a little space to consider the subject from this point of view?

One must distinguish sharply at the outset between (1) the *digestibility* of the milk and (2) its *absorbability*. By the former I mean the ease with which it is peptonised in the stomach; by the latter the extent to which it enters the blood and is available for purposes of nutrition. Jessen,[1] experimenting on healthy men found that a pint of *raw* milk has completely disappeared from the stomach in three and a half hours; a pint of *boiled* milk in four hours. Verhaegen,[2] however, found that boiled milk required less time for digestion than that, while Reichmann[3] even goes so far as to state that 300 cubic centimetres of boiled milk remains for an hour less in the stomach than an equal quantity of milk taken raw.

It is obvious from this that the results of experiments on the relative digestibility of boiled and unboiled milk are not unanimous, but at all events boiled milk has not been proved to be much *less* digestible. Any one, moreover, who has taken the trouble to compare the relative density of clot formed by raw and by boiled milk under the influence of rennet must have recognised that any slight difference there may be is certainly in favour of boiled milk and not the reverse. And yet it is the density of the clot which determines the ease or otherwise with which milk is disposed of by the stomach.

As regards the comparative *absorption* of boiled and unboiled milk experiments have also yielded rather discordant results. Randnitz[4] found that dogs did not absorb the casein of boiled milk quite so well as that of raw milk, but the absorption of fat was the same in the two cases. Vassilieff[5] found that the nitrogen and fat of raw milk were better absorbed by healthy young men than the same ingredients after boiling, but this conclusion is disputed by Gaschibowsky.[6] It has also been found in the case both of infants and of calves that sterilised milk which has been kept at or about the boiling point for more than an hour is absorbed quite as well as milk which had merely been boiled in the usual way.[7]

The supposed loss of nutritive matter in the "skin" which forms on boiled milk is not of any real importance. 100 cubic centimetres of milk when boiled for 15 minutes lose only 0·273 gramme of proteid[8] As a matter of fact the "skin" consists largely of phosphate of lime of which there is already too much in cow's milk.

It is my habit in out-patient practice at the Hospital for Sick Children to order that the milk shall be boiled in every case. Amongst several hundreds of infants so fed I have but rarely had any difficulty in obtaining the normal increase of weight. This is not a mere general impression, for I make a point of having these children weighed every week and a careful record is kept of the increase in weight and the exact method of feeding. I am convinced that such satisfactory results as I find to be the rule could not be obtained if the nutritive value of milk really were, as Dr. Clement Dukes asserts, greatly impaired by boiling.

As regards the supposed risk of producing scurvy by the use of boiled milk it will be sufficient to quote the following paragraph from Holt's well-known text-book on the Diseases of Childhood (p. 210).

> Since the introduction of the practice [illegible] feeding the question has been raised ir[illegible] may not be a cause of scurvy. I hav[illegible] question in the records of three institu[illegible] years "sterilised milk" was the standard food for all artificially-fed infants. The number of children under 18 months who have had this diet is nearly 1000. During this period but two cases of scurvy were observed, and in neither case had the child been upon a diet of sterilised milk. However, I have recently seen in private practice two cases of scurvy in which the cause seemed to be prolonged sterilisation at a high temperature—i.e., 212° F. for over an hour. In some of the cases in which the sterilised m[illegible] have been the cause of scurvy [illegible] which was at fault and not the [illegible] under personal observation who [illegible]lised" milk and a proprietary [illegible] he patient recovered although [illegible]ur cases observed by Winkes no [illegible]no substitution of "sterilised" [illegible] three instances had been pro[illegible]ptly recovered. In these cases [illegible]

In any case the risk of scurvy is one of quite secondary importance. All that one has to do in order to obviate it is to see that a little fresh fruit juice is given to the child occasionally.

Everyone will agree with Dr. Dukes that the ideal to be aimed at is a milk-supply of such assured purity that there can be no risk of disease being conveyed from the cow or the dairy to the consumer. But everyone will also agree that, whatever may be the case in such exceptional circumstances as those in which Dr. Dukes has the advantage to be placed, the milk-supply of the great bulk of the community is not yet in this ideal condition. As long as it can be truly said, as Dr. Dukes has himself admitted,[9] that "milk has been shown to be a fertile cause and communicator of disease in communities," and as long as it remains true, as he has also remarked,[10] "that between the cow's udder and the human stomach the milk may be so poisoned as to cause death to the recipient," so long, I am convinced, will the medical profession do wisely to urge that (again to quote Dr. Dukes): "No milk should be drunk until it has been boiled, even although its nourishing value is thereby diminished." That any real proof of this diminution of nourishing value has yet, however, been adduced I, for one, will not admit.—I am, Sirs, yours faithfully,

ROBERT HUTCHISON.

London Hospital College, July 12th, 1901.

To the Editors of THE LANCET.

SIRS,—I believe that this controversy would have been summarily dismissed as rank heresy were it not for the fact that the heretic is such a distinguished man as Dr. Clement Dukes. If it were possible for the milk to be transferred *direct* from the gland to the human stomach there would have been no necessity for either boiling or sterilising it. But in practice we find that by the time milk is actually consumed it has been exposed to numerous foci of infection (both wilful and accidental) and is in consequence charged with countless bacterial forms.

Milk is an exceptionally good medium for the growth of organisms, and they thrive therein without causing any perceptible change in its appearance. With the appearance of acidification some organisms (notably cholera vibrios) are, no doubt, destroyed; but so much time usually elapses that milk in most cases is used up before this occurs.

All these risks can be easily avoided by boiling or sterilising; and there is no evidence on record to show that these methods cause any sensible lowering in the nutritive value of milk.

Dr. Dukes maintains that all that is really wanted is more efficient inspection of cowsheds and dairies. I might as well ask him to apply this reasoning to the water-supplies, to endeavour to prevent their contamination, and to do away with all sand or biological filters. No matter how stringent be the precautions taken, it is as impossible to prevent the entrance of microbes into milk as it is in our water-supplies.

Dr. Fred. J. Smith observes, in THE LANCET of July 6th, p. 50, that he has seen children made "peevish and even seriously ill" by the effects of boiled milk. But is he quite sure that the cause of this is to be found in milk and not elsewhere? And what evidence is there to show that unboiled milk would have given more satisfactory results in the case of those children?

I am, Sirs, yours faithfully,

M. L. DHINGRA, M.D. EDIN.

Albemarle-street, W., July 8th, 1901.

"LEGISLATION AGAINST NATIONAL INTEMPERANCE."

To the Editors of THE LANCET.

SIRS,—I crave your courtesy so far that you will afford me space for a final reply to Dr. Archdall Reid. We have reached that stage in the controversy when the *tu quoque* argument is apt to be used, and I do not desire that this important discussion should flicker out, so far as I am concerned, with Dr. Reid's peculiar view both of logic and summation of facts. Dr. Reid has a little joke (not at my expense but at his own, of course) regarding the presence of a dragon at three minutes past midnight on Nov. 10th, 1900, curling his whiskers on the cross of St. Paul's. He says that if he asserted that the dragon occupied this ecclesiastical situation nobody could disprove the assertion. Now this very example delivers Dr. Reid and his peculiar ideas regarding the nature of proof into my hands. I shall not spare mine enemy. The case of the dragon would be settled for myself (and I imagine for all sensible men) by considerations connected, first, with proofs of the existence of such a creature; next with questions of its ability to scale St. Paul's (Dr. Reid's dragon would possess wings, no doubt); and, thirdly, with the state of Dr. Reid's mind—here I need not say that I imply nothing personal, of course—when he asserted that he saw the whisker-curling operation. If he merely alleged that a dragon did curl his whiskers, without saying that he saw the operation performed, his case would be less worthy of consideration. Now, judged scientifically, I say we have no evidence in this case that dragons exist; therefore, all the rest goes by the board into that sea of speculation in which Dr. Reid's natatory efforts are not likely to keep him afloat very long if he trusts to the dragon illustration as a species of lifebuoy. He asks me for evidence that "acquired" characters are never transmitted. I suggest in turn that such evidence does exist. This is a reasonable view enough, but Dr. Reid, with an eel-like gesture, slips out of his difficulty on the pretence that I ask him to "prove a negative." That strain of his has "a dying fall." I have heard that argument used many times when the task of proving his own case was beyond the powers of an opponent. Suppose I assert that it is impossible that a dragon should have "curled his whiskers on the cross of St. Paul's." Dr. Reid says that I cannot prove my view to be correct because I "cannot prove a negative." Am I to take it, then, as a corollary of this monstrous proposition, that Dr. Reid asserts that, say, a lunatic's ideas cannot be contradicted? The real case is, that Dr. Reid and myself are both face to face with certain facts of inheritance and each of us seeks to explain them. He chooses one explanation; I choose another. I do not deny that congenital characters are inherited, but I contend that acquired characters may also be transmitted. It is no question of "proving a negative" at all; it is a question whether Dr. Reid's exclusive view as regards "acquired" characters is to prevail. If he has no stronger argument to offer than his dragon illustration as against my contention he must be indeed in "a parlous state." One word more. Dr. Reid professes to scout Spencer, Eimer, Hertwig, Cunningham, and other advocates of the view that "acquired" characters may be handed on. Nobody asks him to "review the works of Spencer" in THE LANCET, but this rejoinder of his, I hope, none of your readers will regard as disposing of the fact that some of our most distinguished biologists are opposed to the Weismannian and Galtonian doctrines tooth and nail. Already I have referred Dr. Reid to cases reported in your own pages. He will find others in Eimer's and Hertwig's works. He says nothing, for example, of the experiments I alluded to on the division of ova, each division reproducing a perfect animal, and yet he avers there is no evidence on my side for him to criticise. In a word, Dr. Reid shuts his eyes conveniently to the evidence on the other side, and then, with his optic on the dragon seated on the cross of St. Paul's, asks me to desist from requesting him "to prove a negative." "I ask him for evidence," says Dr. Reid, and in turn I have suggested where he will find it. If he does not care to criticise it—he has criticised a good deal of evidence on his own side in your pages—that is his own affair. Meanwhile let me say that I believe that the whole question of heredity is still *sub judice*. It is sheer folly for Dr. Reid, as it would be folly on my part, to pretend that either of us has reached an adequate explanation of the varied phases of inheritance. But I protest forcibly at the same time against the idea that the advocates of Weismannian or Galtonian doctrines have proved their case as against the heredity of acquired characters. That case, as pushed to extremes, may, at present, be adequately represented by Dr. Reid's ecclesiastically minded dragon.

I am, Sirs, yours faithfully.

Edinburgh, July 6th, 1901. ANDREW WILSON.

EPSOM COLLEGE.

To the Editors of THE LANCET.

SIRS,—I beg to thank you warmly for your admirable leading article in THE LANCET of July 13th, p. 90, on the position, aims, and difficulties of Epsom College—nothing could be better. But there is one error in your report of my observations at the dinner that needs correction. The amount collected and expended upon the pensioners and foundation scholars within the past 14 or 15 years has been between £70,000 and £80,000, not between £17,000 and £18,000.

I omitted to state that by the will of the late Mr. J. F. France, ophthalmic surgeon to Guy's Hospital, he has left about £10,000 to found additional pensions for *medical men*, to be awarded at the discretion of the council upon which he had served nearly 50 years. He had also arranged to complete the purchase of a tenth scholarship for girls at the schools of the Royal Asylum of St. Anne's. These also are entrusted to the council to award. Altogether my old teacher has expended £22,000 on the purchase of these scholarships for young girls at St. Anne's and in providing for these additional pensions for aged medical men.

I am, Sirs, yours faithfully,

C. HOLMAN,
Treasurer of Epsom College.

27, Soho-square, W., July, 1901.

"THE ARMY MEDICAL SERVICE."

To the Editors of THE LANCET.

SIRS,—Following your recent leading article on the above subject in which you express regret for the absence on the committee of reorganisation "of an army medical officer of high administrative rank and experience" and "trust that the committee will be empowered to call any witnesses whom they may desire to examine," and the reply of the Secretary of State for War in the House of Commons on July [illegible]th that "the committee was a consultative one." only, that "the proceedings would be private" and that they "would not take evidence," one turned to your issue of July 13th in the hope of finding some reference to the position taken up by the War Office as narrated in the replies to the questions asked by Dr. Farquharson and Sir Charles Dilke, and in the absence of such will you allow me to make a few remarks?

I take it for granted that the department will concur in th views which you express in the article in question; and, indee without a member on the committee of high army medic rank "with a knowledge of military organisation and the re quirements of field medical service," it is difficult to understan how the outcome of this scheme placed before the committe emanating apparently from the War Office itself irrespective o the Army Medical Office, can adequately meet the arm wants and solve the difficulties under which the Roya Army Medical Corps labours. It is true that this com mittee comprises the names of professional men of hig civil standing, a lieutenant-colonel of the Royal Arm Medical Corps who also represents Ireland and the pro fessional head of the India Office, yet, with the one limited exception, it members cannot possess that practica knowledge of the medical needs and the details of army routine organisation and command bearing on the efficient performance of the duties placed upon the corps, which is the outcome of "having gone through the mill" and of experience of "where the shoe pinches", nor can they fully gauge "the general medical requirements of the army they are invited to consider" when deprived of the only means capable of eliciting the needs—the evidence of those who have "borne the burden and heat of the day" We have heard much lately of War Office reformation based on business principles, *yet in respect of the medical section the* primary essential to success—probing of the defects and laying bare the wants and opposing conditions to efficient work by interrogation of those having practical knowledge and experience of details—is ignored And this committee, on whom so much public interest is centred and on whose conclusions so much of future army results depend for good or ill will work in private and "the terms of reference" placed before them it is "not proposed to publish"!

Well, Sirs, this committee is formed for the purpose of redressing the past and preventing the recurrence of the complaints which have given it birth yet it must be apparent to anyone who glances over the past 30 or 40 years that the military authorities might have retained the goodwill of the profession which it had in 1860 61 and obtained an efficient body of professional men by making the conditions palatable to men of good standing and such as would permit of efficient performance of the duties placed upon them, and so have obviated the present necessity for action, but what do the facts of the past 30 or 40 years reveal but a condition of affairs, excluding from the purview the formation of the Royal Army Medical Corps calculated to alienate the men whom the country required and to oppose efficient organisation and work Any time during that period a well contented department would have advertised itself, and it would only have required the War Office to make its numerical wants known to have met with the response from the profession which it obtained in the early "sixties", but so far from this condition pertaining we know that the contrary was the fact and the results we see in the necessity for the present committee I venture to say that few if any thinking members of the department during the period mentioned had the faintest belief in the existence of a wish on the part of the military authorities for a strong and efficient medical service—indeed, their acts negative such a conclusion, and when the past and the present are taken together the hope of a thoroughly well-organised and well contented corps capable of performing satisfactorily the important army duties placed upon it grows small indeed. In the past it is quite certain that the responsibility for the defects of the department, including the shortcomings in the present war, rests with the War Office sections which have determined the conditions under which the work had to be done, and it is to be desired that in the future it will be borne in mind in assessing responsibility how insignificant a part the Army Medical Service played in the present in formulating the conditions necessary for its vitality and efficiency Indeed, the studied indifference to its wishes and voice constitutes the worst feature in respect to its future well-being

I am, Sirs yours faithfully,
FRANCIS H WELCH, F R C S Eng,
Lee S E July 15th, 1901 Surgeon Colonel, A M S (retired)

THE GENERAL MEDICAL COUNCIL ELECTION

To the Editors of THE LANCET

SIRS,—The Council of the British Medical Association having kindly permitted a meeting to be held at Cheltenham during the annual week it has been arranged to hold a meeting at St Mary's Hall on Friday morning, August 2nd, at 9 15 A M All the Direct Representatives of the profession will be invited to attend and to speak on medical politics and the same courtesy will be extended to all gentlemen who intend to become candidates The meeting will be open to all members of the profession, whether members of the Association or not As it is probable that many gentlemen will desire to speak a time limit will be fixed

I shall be glad to receive communications from any member of the profession who is desirous of taking part in the meeting I am, Sirs, yours faithfully,
T GARRETT HORDER.
32, Windsor place, Cardiff, July 16th, 1901

VELDT SORES

To the Editors of THE LANCET

SIRS,—I am reported in THE LANCET of July 13th, p 82, in the account of the meeting of the Pathological Society of London held on July 3rd, as saying that the coccus of the veldt sore "would grow in a moist heat of 86° C, in a dry heat of 110° C, and it had retained all its virulence in a dry film for 61 days This should read the coccus would survive and grow after being subjected for five minutes to moist heat of 86° C, dry heat 110° C, or prolonged drying for 61 days

I am Sirs, yours faithfully,
Middlesex Hospital, July 16th, 1901 N BISHOP HARMAN

"BRITISH MEDICAL MEN AND GERMAN WATERING-PLACES"

To the Editors of THE LANCET

SIRS,—I read with a mixed feeling of interest your correspondent's article about British Medical Men and German Watering places I wonder how many of the gentlemen who carefully inspected these watering places have inspected in the same manner the watering places at home

I also have paid visits to most of the German watering-places before I wrote my work on "Sea Sickness and Health Resorts," but I am glad I did not neglect to visit the English watering places first I maintain that the majority of cases sent to German watering places would do much better if sent to watering-places at home, besides saving themselves great fatigue, expense and many of the *social disadvantages associated* with these German watering-places

The majority of the cases which are sent or go to Germany for Schott s treatment return without any benefit and would improve much better under ordinary treatment at home on account of the cases being unsuitable for Schott s treatment

A German doctor in conversation once said to me that the English doctors were always grumbling about the profession being so poor, yet, he said "you send all your rich patients abroad and keep all the poor ones at home" There is a good deal of common sense in this remark. I think a medical man should always consider whether there is not an English watering place where he can send his patient in preference *to sending the patient abroad*, *further, if he is not acquainted* with the properties of any springs, let him write to one of the local men and he will be sure to receive a courteous reply giving him every information

I should very much like to see the faces of a number of German doctors if it was proposed to them to come and visit our watering places with a view of learning their advantages and sending their patients I am sure it would be a study

There are I know, certain diseases that are more benefited by certain German waters and I further know that there are a certain class of people who will go to German watering places, but I protest against sending our patients over wholesale and forgetting we have watering places at home

I am, Sirs, yours truly,
Manchester square W July 15th 1901 THOMAS DUTTON

"THE CONTAMINATION OF POST-OFFICES"

To the Editors of THE LANCET

SIRS,—With reference to the letters which have recently appeared on this subject in THE LANCET it cannot be too clearly understood that it is maintained by those who are opposed to the present action of the Postal Telegraph Clerks' Association that if the course suggested by that association were adopted it could supply *no guarantee that any needful* sanitary alterations in post office buildings would be carried out

Before, however the assertions made by your correspondents can be accepted as evidence of their aptitude to mould public opinion on these matters it would be well that the public should be enlightened in the very numerous inaccuracies with which their letters abound. In Mr Belderson's letter a very strong point is endeavoured to be made from Mr Balfour's statement on June 7th in the House of Commons that every one of the Tweedmouth recommendations had been carried out A careful perusal of his letter discloses most extraordinary confusion on the part of its writer who in his numerous references to the proceedings before Lord Tweedmouth's Committee has apparently entirely failed in distinguishing between the report of that committee and the evidence which was submitted to it. Lord Tweedmouth's Committee did not in its report state that "much still requires to be accomplished before the post-office buildings of the country will be placed in a universally satisfactory condition as regards their sanitation," nor did it "lay down several canons for the guidance of the officials." On the contrary, the following was its report and so important is this matter that I trust you will pardon me for quoting it *in extenso*:—

> *Sanitary arrangements.*—A good deal of evidence was given as to the alleged insanitary condition of certain post-offices. No doubt in some few cases owing to the rapid development of post-office work and the consequent increase of the staff the offices may not be in all respects satisfactory, but the Post Office appears to us to take all possible steps to remedy such cases, and it is kept acquainted with the actual condition of the large post-offices throughout the United Kingdom by annual reports from its local medical officers. A large number of these officers have furnished us with reports on the offices which they inspect, and these reports appear to us to be on the whole very satisfactory.

Again, as further evidence of the want of accuracy on the part of those who are pioneering this movement for the Postal Telegraph Clerks' Association, reference is made by Mr. Belderson to the knowledge of Dr. Ransom of the unsatisfactory condition of the new Nottingham post office. I am in a position to state that it is known that inquiry was made of Dr. Ransom in connexion with certain statements which he had seen fit to make and that it was found he had absolutely no personal knowledge of the condition of that building beyond the very limited one of the public office, upon which evidence it transpired he had based his assertions.

Again, with regard to Mr. Garland's allegations in THE LANCET of June 29th, p. 1860, as to the excessive prevalence of tubercle amongst telegraphists and his attributing it to the insanitary conditions of post-office buildings, it is worthy of note that the medical officers have for years interested themselves in this subject and only recently have collected statistics concerning it. These statistics just issued reveal that this disease exists only to a very limited degree amongst all grades of postal employés, and that its greatest incidence is found to be not on the telegraphists but on the letter-carriers. A feature exhibited by these statistics which in the present agitation should not be lost sight of is that in a considerable number of cases the faulty dwellings and habits of the men have been held to have been provocative of the disease, and in conclusion this impels me to raise the question, Do these men who are now making such urgent demands of the Government and on the public purse strive to maintain as high a standard in the hygienic conditions of their homes and home life as that they now insist upon as essential when engaged in their work for the public? I fear not.

I am, Sirs, yours faithfully,

July 13th, 1901. P.M.O.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Plague Epidemic.—The Famine.—An Invasion of Locusts.

THE mortality from plague for the whole of India has further declined from 847 in the previous week to 683 for the past seven days. The Bombay districts seem to remain stationary. In Bengal the disease has rapidly subsided and in the affected districts only a very few cases are now reported. In Calcutta the deaths are only about 20 per week. In Bombay city also there is a distinct improvement. I have previously remarked on the similarity of course pursued by the several outbreaks in these two cities, but Calcutta has never been so severely attacked as Bombay. With each year, however, there has been an increase in Calcutta In the 1889 outbreak there were 1336 seizures and 1223 deaths in addition to 835 suspicious cases. In the 1900 outbreak there were 7897 seizures and 7373 deaths. This year's outbreak has brought 8135 seizures, with 7410 deaths. The deaths from plague have almost entirely accounted for the excess in the general mortality, showing that the system adopted for discovering and reporting plague deaths must be fairly accurate This result has not been arrived at by calling every case plague which cannot be put down to any definite disease, as has been done in many places visited by the epidemic, but by detailed examination of the reports of the medical officers into the history of every death.

The famine returns for last week show an increase of 14,000, of which 12,700 were in the British districts of Bombay. The total under relief at the present time amounts to 520,000 persons.

A large part of India has recently been subjected to an invasion of locusts Swarms have been seen from Beluchistan on the west to Assam on the east. In some districts they have merely passed over without doing any damage; in others slight injuries to the crops have resulted; and in a few places considerable destruction has been experienced. The danger is not so much from the mature insect as from the young. The places where the swarms settle and lay their eggs are always the chief sufferers. The plan generally adopted is to plough the land and thus to bury the eggs, but where these have hatched and the young, wingless hoppers have commenced by their voracious feeding to clear every eatable plant, it is necessary to dig trenches, to drive the immature insects into them, and then to bury them, or to strew the affected land with straw soaked in petroleum and to set fire to it. It is anticipated that unless this is done on an extensive scale for the present visitation enormous destruction of crops will result. Some of the papers are already calling for Government help in the matter. In some districts numbers of dead locusts have been discovered, and they appear to have died from a worm (?) disease, as the thoraces of the infected insects are infested with maggots. These specimens have been sent to Calcutta for examination. Perhaps, after all, nature will provide a remedy.

June 29th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Electric Wire Fatality.

THE electric tramways in Manchester have claimed their first victim. The deceased, a man in the employ of the corporation, was assisting in the changing of an "anchor wire." He went up a ladder, which was not part of his duty, and touched a "live wire." His fellow workman heard a cry and looking round saw deceased "with fire coming out of his hands in the act of falling from the top of the post," which he had reached by climbing the ladder. He fell about 22 feet, alighting on his head. He was taken to the infirmary where he died soon afterwards. The point that was brought out at the inquest which was held on July 12th was that ignorance often, and carelessness far too often, bring about these accidents. It is the old story, familiarity with danger inducing disregard of it. As regards warnings, there was some uncertainty as to the man having had any warning of danger. The electrical engineer for the overhead electrical equipment said that the man had not been personally warned by him. He left it to the foreman. In this case the foreman left it to another man, who in his turn almost certainly failed to warn the deceased. The engineer said that he should "accept the coroner's recommendation to warn all the workmen specifically." The invisibility of the danger makes caution the more needful, so it is to be hoped that the coroner's recommendation will be carried out. Overhead-wire dangers were well illustrated in another way at Bolton on July 22nd. "The trolley-head of a car got fast in the span-wire and the force swung round the bracket-arm of a street-pole, with the result that over 100 yards of overhead equipment fell with a terrific crash and illuminated the street. There were some miraculous escapes from the live wires." The system which allows of such incidents as these is not perfect.

Meeting of the Dwellings Improvement Society.

On July 11th a meeting was held of the newly formed "Citizens' Committee for the Improvement of Unwholesome Dwellings and Surroundings of the Poor," Mr. T. C. Horsfall presiding. In spite of its cumbrous title the society may do good, for its objects are unexceptionable. But the multiplication of societies may go too far, and the strength of the forces opposed to the disease-producing conditions of our towns may be weakened by their being broken up into guerilla bands. The objects of this society are all embraced by the Manchester and Salford Sanitary Association, of [illegible] etted that [illegible] o strength [illegible] of land outside the city boundaries, "both for the provision of open spaces and of houses, is absolutely necessary for the welfare of the community." A town's meeting has recently been held under the chairmanship of the Lord Mayor and a resolution in favour of the purchase of the Park was passed, but the city council numbers among its members some who do not realise the value of large open spaces to the health of crowded towns, or the fact that Heaton Park is the only one now left near Manchester, so that the regrettable blunder by which Trafford Park was lost may be repeated on the north side of the city. Mr. F. Scott, the secretary of the Sanitary Association, in seconding the resolution said that at the town's meeting there was a marked line dividing the two sections for and against the purchase of the park. The latter consisted almost, if not quite, exclusively of the property owners and rent-chargers, while the former "included a very large number of working people whose views were voiced from the platform by the chairman of the Trades Council, and who were enthusiastically in favour of the purchase." It has been carefully calculated by architects and others that, without spoiling the park, its "fringe" could be used for building sites, and would bring in an income of £10,000 a year. Another speaker thought that the purchase was all the more essential "when [illegible] system which was [illegible] m of mere breeding [illegible] "Breeding cages" [illegible] n, but it cannot be said to overstate the case. By another resolution the committee seeks "the coöperation of the Sanitary Association, the Ladies' Public Health Society, the Manchester and Salford Housing Reform Council, and other similar organisations." It remains to be seen whether the council will be moved or not. One need seemed to press on the minds of those present—namely, that the members of the council should not be chosen for their political views, as is almost invariably the case at present, but for their intelligent interest in the physical and moral welfare of their fellow citizens. A clerical speaker said that they had solved this problem in Gorton, where they had elected five members on social grounds by taking them equally from the two political parties, a proceeding which suggests a sort of double Hibernicism. The chairman announced that Professor Chapman, who has recently been appointed to the chair of Political Economy at Owens College, had joined the committee. At the meeting of the Parks Committee on July 11th it was decided that in view of the expression of public opinion that has taken place the whole question of the purchase of the park should be considered at a special meeting.

Medical Golf.

The love of outdoor games still exists in and about Manchester among members of the medical profession, many of whom feel quite at home before the wickets or on the golf links. And when one considers the conditions of life for the residents here—for medical men have necessarily to live near their patients—it is satisfactory to know that a fair proportion gain health and refreshment from cricket and golf. Since May 1st a medical golf tournament has been in progress and has just been decided There were 78 entries and the opening rounds were played on the Trafford Park links of the Manchester Golf Club where the final was also played. Dr. J. Massey of Pendleton was the victor and won the challenge cup for the year, together with a replica to be held as a memento, his opponent in the last stage of the tournament being Dr. J. Howie Smith of Stockport, to whom he is doubtless extremely grateful, for without losers no one could win. Both gentlemen, therefore, are to be congratulated.

Another Tramway Danger.

The great natural beauty of the Manchester suburbs has been destroyed long since by the growth of the town, and it is only of late that our senators have become aware that love of the picturesque and beautiful may coexist with reason and good sense. The consequence is that there is only one approach to the town of which its inhabitants can be proud. Of the Wilmslow-road the *Manchester Guardian* says: "Few great manufacturing cities in England can boast of so fine a leafy avenue within easy distance of the centre of the town …… with its ancient elms and limes." Much the same is true of the Palatine-road, but both are said to be threatened by the corporation and the Withington District Council, who, it is stated, intend to cut off part of the gardens to widen the tram-lines. The dwellers on the road are naturally alarmed, but as the *Guardian* says, it is hard to believe that they will not take every precaution to save the trees, and "we may, therefore, fairly expect the corporation to see that the installation of the overhead system does not destroy the peculiar charm of the pleasantest approach to Manchester." And so say we all.

July 16th.

WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

Proposed Sanatorium for Consumption near Bath for the Counties of Gloucester, Somerset, and Wilts.

WITHIN the past few days meetings have been held both at Gloucester and Cheltenham, under the auspices of the Gloucestershire, Somersetshire, and Wiltshire branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis, in furtherance of a scheme for the erection of a free open-air sanatorium for the poorer classes of those three counties The mayors of the respective towns presided. At the Gloucester meeting the chief speakers were Dr. R. Maguire (physician to the Brompton Hospital for Consumption) and Dr. L. A. Weatherly of Bath (chairman of the executive committee of the proposed sanatorium). In speaking of the prophylaxis of tuberculosis and describing the methods by which the disease could be prevented from spreading from one patient to another Dr. Maguire said that it was a great misfortune that some people should think it was a danger to have a hospital for the reception of tuberculous patients near them. During the last month the question had been raised in regard to the Brompton Hospital, which was the first of the kind established, and some people said that it was a danger to the community. The hospital was built in the fields originally, but a very rich neighbourhood of London had sprung up all around it. The number of cases of tuberculosis of the lungs which had arisen in the Brompton Hospital during the whole of the years in which it had been in existence had been very few, and that was because of the care which was taken. If care was taken there was really no great risk of contagion and it was only right that the public should be educated as to the kind of care that was wanted. Dr. Weatherly gave an account of what the committee of the three counties had done, and were hoping to do, with reference to the establishment of the sanatorium. A site near Bath had already been purchased for £2000 and the foundations of the building had been prepared. The total cost of the sanatorium would not be less than £20,000, and it would accommodate 60 patients in the winter and 100 in the summer. At Cheltenham the chief speakers were Professor J. Michell Clarke, of University College, Bristol, and Dr. Weatherly. At both meetings the following resolution was passed unanimously:—

> That this meeting, recognising the urgent need of the building of a sanatorium for the poorer classes of consumptives in the counties of Gloucestershire, Somerset, and Wilts, cordially supports the scheme, and resolves to do all in its power to help it forward by assisting to raise the necessary funds.

Munificent Bequests by a Clergyman.

The Rev. John Balfour Atkinson, rector of Larling, near Thetford, who held curacies in Somerset from 1873 to 1887, has bequeathed £3000 to Guy's Hospital, and to the Royal Infirmary, Edinburgh, £10,000 and the residue of his property. The net value of his personal estate is nearly £60,000.

Cardiff Infirmary.

The board of management of the Cardiff Infirmary have decided to appoint an additional honorary anæsthetist to attend at the infirmary three times a week. There are at present two honorary anæsthetists on the staff of the institution. A suggestion to appoint an assistant gynæcologist was not adopted by the board.

Swansea Hospital.

An anonymous donor has given £1250 towards the refurnishing of one of the empty wards of the Swansea Hospital. At the June meeting of the hospital committee Miss Dillwyn stated that she had had placed at her disposal by an anonymous benefactor the sum of £500 as the nucleus of a fund for the establishment and maintenance of a convalescent home in connexion with the hospital, but at the meeting of the committee held on July 12th she announced that this amount had been increased to £5000 and that she herself would contribute £100 to the fund provided nine other persons would each give an equal amount. The Swansea Trade and Labour Council are desirous of obtaining more direct representation on the board of management of the hospital for the workmen in the town who are said to contribute one-fourth of the income of the institution. A contributor of 25 guineas has hitherto been a life governor and this qualification has now been reduced to 10 guineas, but a proposal that any body of working men who contribute this sum annually shall be entitled to nominate a governor has not been entertained. A rule embodying this proposal has been added only during the present year to the rules of the Cardiff Infirmary. Although it may never be used to the injury of the institution it is full of dangerous possibilities, for practically any body of persons or members of a congregation, or club, or association by subscribing a guinea yearly are entitled to nominate one governor for the year during which the subscription is current. A certain number of groups of 21 persons, each subscribing 1*s.* yearly, might thus obtain absolute control of the institution.

Slaughter-houses at Bristol and Cardiff.

The Health Committee of the Bristol Corporation have under consideration the further provision of slaughter-houses for the city. In his last published annual report (1899) Dr. D. S. Davies stated that there were in Bristol 124 private slaughter-houses and two belonging to the Docks Committee, and he further stated that the position and structure of a large number of the former rendered them unsuitable for the purpose to which they were put. At Cardiff all slaughter-houses were abolished many years ago through the provisions of a local Act and two admirably arranged and well-constructed public abattoirs are the only places in the town where slaughtering is permitted. In the year 1900 there were slaughtered in these two abattoirs nearly 95,000 animals and during the same year about 16,000 pounds of unsound meat were destroyed. It is of interest to compare these figures with those for the year 1896, when 90,000 animals were slaughtered and about 4000 pounds of unsound meat were destroyed. The large increase in the quantity of meat destroyed is no doubt due to increased vigilance in inspection. This is now carried out by the superintendent of the slaughter-houses and his assistants, by an inspector who has had special experience as a butcher and as a meat-salesman, and by a veterinary surgeon whose whole time is given to the service of the corporation. This increased activity on the part of the health department has had the effect of increasing the number of slaughter-houses just outside the borough boundaries, and in his report for the year 1900 Dr. E. Walford discusses the desirability of a more stringent examination of carcasses brought into the borough from outside districts. He admits that at present no power exists for the establishment of such examination, but he suggests that it might be obtained by inserting a clause in a local Bill requiring that all meat slaughtered outside the town and brought into the borough for sale should be taken for examination to a meat station and if passed as sound should be stamped.

Diphtheria in Glamorganshire.

The continued prevalence of diphtheria in Glamorganshire is sufficiently serious to call for some comment. During the past four years the disease has been endemic and has been responsible for a very large number of deaths. In the past six months, in the seven largest towns of the county—namely, Cardiff, Swansea, Rhondda, Merthyr, Aberdare, Pontypridd and Mountain Ash—where there is an aggregate population of over half a million persons, there have been notified 1350 cases of diphtheria, equal to a case-rate of nearly 5 per 1000 per annum. The number in each town ied considerably, the case-rate in Swansea being 1 per Merthyr 2, in Cardiff 3, in Aberdare 4, in Mountain dda 9, and in Pontypridd 11 per 1000. (The e been omitted in these calculations.) The lerthyr has been hampered in his endeavours to stamp out the disease by the insistence of prominent members of the Health Committee that the epidemic is entirely due to the impure water which is said to be supplied to Dowlais, where a large proportion of the cases have occurred. The danger of allowing the inhabitants to take this erroneous view lies in the fact that though they may refrain from drinking the water they will still continue to visit and to hold religious meetings in infected houses and in many other ways they will spread the disease by personal contact.

Cardiff Cottage Homes.

It has been admitted by the Cardiff Board of Guardians for some time past that increased accommodation would have to be provided for the indoor paupers of the union. A suggestion to erect a new workhouse, which it was estimated would cost about £40,000, met with little support, and it has been alternatively decided to build grouped cottage homes for 72 children. Plans for this institution were adopted by the board on July 5th. The architect, Mr. E. Seward of Cardiff, has provided for an administration block, a detached cottage to accommodate 24 children, with a bedroom for the father and mother and a bedroom for a relief mother, and two detached and two semi-detached cottages with accommodation in each for 12 children and a mother. The total cost of the scheme exclusive of the site is estimated at £6000.

Bristol Municipal Lodging House.

The corporation of Bristol have decided to follow the example of Salford, Southampton, Manchester, and other towns and to erect a municipal lodging-house. There will be accommodation for 120 men and the cost, exclusive of furnishing, is estimated at £7100 or about £60 per bed, a sum which compares favourably with that which was expended at Salford, or at Southampton, or by Lord Rowton in his first venture at Vauxhall. At the Salford lodging-house there is accommodation for 285 men and at Southampton 186 can be accommodated.

July 16th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The School of Medicine of the Royal Colleges, Edinburgh.

AT a meeting of the governing board of the School of Medicine of the Royal Colleges, Edinburgh, the secretary, Mr. R. N. Ramsay, reported that the number of students attending the school during the winter session 1900-1901 was 1160, and during the summer session 1901 the number was 1119.

Appointment of an Aberdeen Lady Medical Graduate.

Miss Myra Mackenzie, M.B., the first lady medical graduate in the history of Aberdeen University, has been appointed house surgeon to the Sick Children's Hospital, Sheffield.

Small-pox at Peterhead.

Last week it was reported to Peterhead Town Council by the medical officer of health and the sanitary inspector that owing to the vigorous measures adopted in view of the proximity of the herring fishing there was no danger of small-pox spreading, the case that had been treated in hospital being convalescent, while the family would remain a week or two longer in hospital. It was stated that a very suitable house for the reception of "contacts" had been obtained and would be occupied so long as was necessary.

Glasgow University.

At a meeting of the University Court of Glasgow University on July 11th, it was announced that under the will of the late Mrs. M'Roberts of Todhill a sum of £10,000 had been bequeathed to the university for the purpose of founding and endowing a chair as the court may direct. On the recommendation of a special committee the court decided to give effect to the resolution of the general council of the university, and to take the steps requisite to institute the degrees of B.Sc. and D.Sc. in the department of public health, and authority was given for the preparation of a draft ordinance prescribing the regulations for the courses of study and for the examinations in connexion with these degrees. A proposal to fit up glass cases on the walls of the Randolph Hall for the reception and display of the illuminated addresses presented on the occasion of the ninth jubilee was adopted. There was no other business of general interest. The final examinations for degrees in medicine which have been in progress during the last three weeks have come to an end and the list of successful candidates has been issued. The graduation ceremony is expected to take place near the end of the month.

Small-pox Hospital Accommodation in Glasgow.

The recent epidemic, now happily a matter of history, has taught the authorities, among other lessons, the necessity for increasing their arrangements for the reception of small-pox patients. It was found that to send these patients to the hospital at Belvedere, where infectious diseases in general are received, had many disadvantages and a special committee was appointed to deal with the question. At a recent meeting of the town council the committee reported in favour of the erection of a new hospital and were authorised to select a site and to obtain plans. Dr. Carswell announced that several sites had been inspected and that the contemplated arrangements would be fully adequate to meet the highly improbable event of a renewed outbreak of the disease.

St. Andrews University.

The trustees of the late Miss Malcolm, sister of Sir James Malcolm, Bart., of Balbedie, have intimated that a legacy of £4000 has been left to the university for the purpose of establishing medical bursaries or scholarships.

New Hospital for Consumption at Perth.

The new hospital for the treatment of consumptive patients, erected at a cost of £10,000 by Sir Robert and Lady Pullar of Tayside on the western slopes of Kinnoull Hill, Perth, was formally handed over to the Society for the Relief of Incurable and Chronic Cases on July 15th. The ceremony took place in the presence of a large and distinguished company, and an inaugural address was delivered by Sir William Gairdner, K.C.B. The hospital is well sheltered from the north and east and stands in its own grounds, which extend to about six acres. Accommodation is provided for 20 patients. A determined endeavour is being made to secure an endowment for at least eight of the beds, so that the authorities may be able to receive a certain proportion of patients from the very poorest classes. This will need a sum of £10,000 and towards this nearly £5000 have already been received.

(FROM OUR OWN CORRESPONDENTS.)

Board of Superintendence of the Dublin Hospitals.

THE annual report of the Board of Superintendence of the Dublin hospitals has recently appeared. It states that during the year ending March 31st, 1901, no culpable irregularity on the part of nurses or attendants was brought before the notice of the board. They note with regret that the interest taken, as indicated by the attendances of the governing bodies at their various meetings, leaves much to be desired. The board are of opinion that the holding of "wakes" in tenement houses, condemned by all religious and medical authorities, might be to a great extent prevented if suitable mortuaries were established in the different parishes. The report states that the board are gratified to observe that the medical staff of each hospital (with the exception of one) is now represented on the governing board by some of its members. As regards statistics, the number of patients admitted during the year to the hospitals under the supervision of the board was 11,601, the total daily average number of beds occupied in the hospitals covered by this report being 946·05. The time spent in hospital by each patient under treatment (omitting the patients in the Royal Hospital for Incurables) averaged 24·16 days.

Tuberculosis in Ireland.

In a notice of the forthcoming Congress on Tuberculosis the *Irish Times* calls attention to some recent returns of the Registrar-General for Ireland dealing with the subject. They show that in 1899 79,699 deaths from all causes were registered in Ireland and of these no less than 12,812 were caused by tuberculosis. It appears thus that the deaths from tuberculosis are far more numerous than those caused by zymotic diseases, although the latter include scarlet fever, small-pox, measles, diphtheria, epidemic diarrhœa, typhus fever, typhoid fever, cholera, dysentery, whooping-cough, influenza, puerperal fever, simple continued fever, and ill-defined fever. The mortality caused by all these taken together was for the year 1899 8857, or only two-thirds of the number attributable to tuberculosis alone. In Dublin 1200 people die each year, while in Belfast there is an annual mortality of over 1000. Modern pathological research tends every year to add to the number of diseases traceable to tuberculous infection—e.g., the chronic abscess and the enlarged bursa. It seems probable that for this reason alone the returns of deaths from tuberculosis will largely increase.

The Conference of the British Pharmaceutical Societies.

The British Pharmaceutical Conference will be held in Dublin on July 29th when the proceedings will be opened by a reception by the President at the Museum of Science and Art. The President for this year is Mr. G. L. Druce, M.A., F.L.S., Mayor of Oxford. The visitors, of whom between 400 and 500 are expected, will be welcomed by the Lord Mayor of Dublin and will hold their scientific meetings in the lecture theatre of the Royal Dublin Society.

County Antrim Infirmary.

At a meeting of the Board of Management of the County Antrim Infirmary, held in the board-room of the hospital, Lisburn, on July 11th, a committee was formed to draw up a representation for the County Down County Council asking them—in reference to the admission of patients—to contribute towards the expenses of that county's patients. It was suggested that in order to increase the finances a fancy fair and bazaar should be held.

The Outbreak of Typhoid Fever in Belfast.

At the meeting of the Public Health Committee of Belfast on July 11th a report in reference to the outbreak of typhoid fever was presented by Dr. A. G. Robb, visiting physician to the fever hospital; by Dr. J. Fulton, medical officer of health of No. 10 Dispensary District; and by Dr. H. Whitaker, medical superintendent officer of health of Belfast. These medical men made a careful inquiry into the history and probable cause of the onset of typhoid fever in a list of 24 houses supplied to them, the number of cases of typhoid fever being 27. In their endeavour to arrive at the cause of onset they quoted the evidence under the following headings: 1. Date of first appearance of the disease. This varied widely from the end of March until the beginning of June. In the latter half of May in a considerable number the disease first appeared. 2. Sanitary state of houses. The large proportion of these houses are of modern construction, built on good ground. With three exceptions they are provided with back passages; with one exception they have water-closets. In no case was there a cistern, all drinking-water being drawn direct from the main. With three exceptions the yards were in good condition, well drained and trapped. In a few cases, however, they proved evidence of the greatest carelessness and disregard of sanitary habits on the part of the inmates. In some, where there were good water-closets in good working order, these closets were apparently little used, deposits of fæces being found all over the yards 3 Careful inquiry into the possibility of infection from food supplies failed to elicit any satisfactory evidence of infection in that way. 4. Milk-supply. In two houses condensed milk was used, in four there was no regular supply of milk, while the remaining 18 houses drew their milk from 13 different sources. Inquiry at these 13 places of supply failed to elicit any evidence of the possibility of infection by that means. 5. Water-supply. These houses are supplied with the Stoneyford water. The medical men appointed visited the gathering ground in the Stoneyford catchment area, and they report that they found abundant evidence of the direct contamination of the Stoneyford reservoir with alvine discharges, both brute and human, and that but little change had occurred therein during the last three years when two of the sanitary sub-officers reported that "the drainage of a number of farmhouses, stables, manure-heaps, &c., discharges either into the subsoil or into the adjoining streams or water-courses." They found that two cases of typhoid fever had occurred in this area in different houses on Feb. 5th and 28th last; one of the patients died and the other had been removed to hospital after a week's illness. They think that it is impossible that the reservoir could have escaped contamination from these cases of typhoid fever at that time. They give details of cases where from farms in the district the reservoir was contaminated. From the house from which the patient was removed with typhoid fever the drainage of the farmyard and manure heaps discharges into an open drain in front of the dwelling-house and thence directly into an adjoining stream which communicates with the reservoir. In their conclusions the medical men report that in the majority of these cases the onset occurred at the end of the long period of dry weather in the month of May and seems to have been connected therewith. Owing to the very unsanitary habits of some of the inmates of these houses and the consequent certainty that the soil of the yards must at times become polluted with the dejecta of typhoid fever patients, they believe that so long as patients are treated in this careless manner in their own homes secondary cases must frequently arise from this cause, and that sometimes the lapse of time between these cases may be many months and may be determined by long periods of dry weather. The evidence they observed of the pollution of the Stoneyford reservoir with sewage matter from the numerous farms still occupied in the catchment area, and the evidence of direct contamination with sewage from houses in which typhoid fever had recently occurred, leads the medical men to believe that the water-supply is mainly responsible for the excess of typhoid fever in the district. It is satisfactory to know that there is a considerable decrease in the number of cases notified during the past week.

Close of the Summer Session at Belfast.

The summer session came to a close last week, and at the Royal Victoria Hospital most of the senior medical men are going off duty for the next two months.

July 16th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Paris Municipal Council and the Discharge of Infectious Cases from Hospital.

M. MARSOULAN recently brought before the Municipal Council the case of the mother of a family one of whose children had been treated at the Trousseau Hospital for diphtheria. The mother, despite the cruelty which her action entailed (for the child was at the last gasp), could not allow her son to die in the hospital and took him home. The director of the hospital tried in vain to persuade the mother not to take the child with her, pointing out that he would spread infection in the dwelling to which she took him. But nothing could shake her determination to remove him. There is no law under which the director of a hospital can refuse to allow a patient who is the subject of infectious disease to go, or to be taken out, before recovery, and M. Marsoulan rightly urged that all attempts to prevent the spread of infectious disease, such as isolation wards and antiseptic measures, are not of the least use so long as they are all made to give way to a mother's wishes. M. Marsoulan asked the council to take such measures as would give powers to the directors of hospitals by the exercise of which they could render of some effect the efforts which are constantly being made in the cause of hygiene and public health. M. Marsoulan demanded urgency for the following motion. "That as soon as possible a law should be passed by which directors of hospitals or other establishments in which cases of infectious disease are treated should be empowered to prevent such patients leaving the hospital before recovery." This motion was unanimously carried.

Railway Hygiene.

The Minister of Public Works has just addressed a circular to the railway companies wherein he recommends that the following measures should be taken with regard to the carriages and waiting-rooms. All floor coverings other than those made of linoleum or indiarubber or other easily cleansed material should be done away with. Sweeping and dry cleaning should be forbidden and be replaced by sluicing with a hose or rubbing over with a cloth wrung out of some antiseptic fluid. Pending a supply of plain cushions (which should not be buttoned down or have any folds in them) covered in some impermeable stuff which can be frequently cleansed all cushions and padding should be covered with loose covers which should be from time to time disinfected in a stove. The circular further lays down that passengers who are obviously suffering from infectious diseases should be made to travel in a special carriage which on arrival at its destination should be disinfected. Everyone will approve of these rules in so far as they bear upon cleansing and especially in the suppression of buttoned-down cushions. But the last clause will be most difficult of application. Neither the public nor railway employés are capable of deciding whether or not a person is obviously suffering from an infectious disease.

Brewer's Yeast as a Test for the Intercommunication of Springs.

At the meeting of the Academy of Sciences held on June 17th M. Miquel pointed out that it was easy to ascertain whether a well or a water-course communicated with a spring, which it might be necessary to take up as a water-supply, by throwing in a little brewer's yeast which was afterwards sought for in the water which it was desired to take up. Some of this water was to be placed in a mattrass kept in a stove at a temperature of 25° C. To every 1000 grammes of water there were to be added one gramme of tartaric acid and 200 grammes of saccharose. If the water contained yeast an active alcoholic fermentation was set up in from 24 to 48 hours. Yeast preserved its vitality in water for a long time and had been known to exhibit fermentative powers after being two months in an aqueduct 100 kilometres in length. The amount of yeast used varied according to circumstances from 10 to 40 kilogrammes.

The Law as to Workmen's Compensation and Medical Aid.

When the law as to compensation for accidents to workers came into operation everyone said that it was very imperfect and would very shortly have to be revised. No one was satisfied, neither the workmen nor the masters, and as to the medical men on whose coöperation the whole law depended it was quite obvious that as usual they were expected to give advice as a matter of charity. Modifications with regard to the following clauses have just been brought before the Chamber of Deputies. 1. The right of choosing a medical man. 2. The rate of payment of expenses. 3 The treatment of the injured in hospitals. As regards the first proposal medical men have, thanks to the efforts of M. Dubuisson, obtained this boon. The Chamber has decided that the injured man can be attended by any medical man and be supplied with medicine by any apothecary whom he may choose. This is an important modification, although it is only the application of an old rule which existed by the law of 1898 but was not very evident. As regards payment, by the law of 1898 legislators did not dare to propose that treatment of injured workmen should be gratuitous, although the certificate as to the origin of the wound was ordered to be given gratuitously. They remembered, however, that by the law of July 15th, 1893, poor persons were to be attended at a special rate and that a very low one. Accordingly in 1898 they decided that workmen injured in the course of their employment should be attended at the same rate—namely, that of the Assistance médicale gratuite. As far as the really indigent were concerned medical men had no objection to charging a very small fee, but as regards workmen injured during their employment they stood upon quite a different footing. They were not indigent, but workmen on full pay. If they had received an injury apart from their work they would have called in a medical man and would have paid him according to their means. They were workers and the law said that their employers should pay; this was not out of charity, but as a principle of justice which made the employer responsible for an injury caused by some agent which was gaining profits for him. This being so, the employer is certainly not an indigent person, and all the less in that he is protected by being insured. Insurance companies are rich, and why, then, should medical men give gratuitous attendance to a workman whose employers pay a fee which they finally get out of the insurance company? Why should a medical man give gratuitous attendance simply, as finally happens, to benefit the shareholders of an insurance company? The Chamber of Deputies has, however, adopted the usual scale of medical pay which is in use by the Assistance Publique. M. Poulain demanded in company with the Socialists that any workman should have the right of being treated at his own home, even though seriously injured. The Chamber did not agree. Every hospital in Paris or the provinces was at the service of the insurance companies. The President of the Committee argued that he could not promise that a workman would be treated at his own home, but he could if he went to a hospital where he would be well cared for and where his recovery would be more rapid and more certain. This argument is false. Apart from very severe injuries there is no proof that a workman would not get well quite as quickly at home as in a hospital. Take, for example, fracture of the leg, a common enough accident. Why should a workman take up a hospital bed for 40 days rather than occupy his own bed for the same time? M. Poulain argued that in cases where it was necessary the medical man in attendance should be allowed to call in a consultant. But the Deputies would not listen; they put all the hospitals at the free disposal of the insurance companies so that a medical man practising in a factory town will see all his working-class surgical cases swept into hospital before his face

July 15th.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

Treatment of Whooping-cough.

DR. THEODORE ZANGGER has issued a *résumé* of upwards of 100 cases treated principally by preparations of quinine, which in the later cases was combined with hydrotherapeutic measures. The cases referred to were children under six years of age, the youngest being two, five, and eight weeks respectively. There was no fatal case observed, though five cases came under treatment with single pneumonia, sometimes of a very severe type. The number of paroxysms of whooping-cough never exceeded 32 in 24 hours, and they decreased rapidly during the second week of treatment. The general state of health on discharge, generally after two, three, or four weeks of treatment, was often so good that a change of air seemed unnecessary. Tannate of quinine proved of little effect; the best results were obtained from hydrochlorate of quinine dissolved in water and administered in milk in doses of from one to three grains three times a day before meals, according to the age of the patient. Very good results were also obtained from the exhibition of euchinin in the form of a powder, which has the advantage of being almost tasteless and can more readily be administered to children. The dose varied from two to six grains two or three times a day before meals. Wet packs reaching from the armpits to the ankles had a very soothing effect, when properly applied and well covered with flannel, and were left on for two or three hours or for the whole night; in case of concomitant pneumonia they can be renewed several times in 24 hours.

Sanatorium for Consumptives.

Dr. Staub, director of the Zürich Cantonal Sanatorium for Consumptives at Wald, the altitude of which is 900 metres above sea level, states in the second annual report for 1900 that a total of 231 patients was admitted, mostly poor people, for whom the daily sum of 2 francs (1*s.* 7½*d.*) had to be paid either by the parish or by private benevolent institutions if they or their friends could not pay this small sum. The results were nearly as satisfactory as in the previous year; 183 of the patients, or 79 per cent., were dismissed "improved," and 59·3 per cent. were fully capable of resuming their usual occupations. Financially the sanatorium is progressing well owing to the support of the public, it is free from debt, and it closes its yearly account with a credit balance of over £300. The cost of a single patient per day is 3*s.*, so that a deficit of £1350 was covered by the yearly subscriptions and gifts

Zürich, July 15th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Plague.

THE bubonic plague still lingers on in Queensland where several fatal cases have occurred Its existence in Brisbane necessitated an alteration in the movements of the Duke and Duchess of Cornwall. The original intention was that they should go to Brisbane by sea, but Brisbane having been proclaimed an infected port the Royal yacht would have run risks of quarantine had she gone there, so the Royal party went overland by train. It is high time that the Australian system, or rather want of uniform system, in regard to quarantine should be reorganised. It was expected that it would be one of the first things to receive attention under the Federal Government, but so far nothing has been done and every day fresh muddles occur.

Health of Melbourne.

The annual report of the Health Office of the city of Melbourne for the year 1900 is a satisfactory document. The death-rate was only 12·97 per 1000, lower than in any previous year. The average mortality for the last five years was 14·23, as against 16·29 and 19·54 for the previous quinquennial periods. The mortality from epidemic disease was low, a total of 30 as against 73 in 1899 and 106 in 1898. There was also a large reduction in the mortality from diarrhœal diseases, and among infants tuberculosis caused the greatest number of deaths, and there was no decline noticeable in its prevalence or fatality. During the year improvements in dwellings had been largely effected, 222 houses were repaired, 36 pulled down, and 11 vacated under orders from the Health Committee.

Sydney Hospital.

The Board of Management of the Sydney Hospital have just completed a handsome building at Paddington to be used as a branch dispensary for the eastern suburbs. The following appointments have been made in connexion with this dispensary: assistant physician, Dr. G. M'Lean; assistant surgeon, Dr. C. E Corlette. Dr. Richard Arthur has been appointed assistant surgeon to the throat department at the main hospital

Sydney University.

At the last monthly meeting of the senate of the Sydney University it was reported that the following courses of optional lectures would be delivered in the Faculty of Medicine.—Diseases of the Skin, by Dr. F. A. Bennet; Diseases of the Ear, by Mr. G. T. Hankins; Demonstrations in Psychological Medicine and Neurology, by Dr. J. F. Flashman; Diseases of Children, by Dr. A. E. Mills; and the Ethics of Medical Practice, by Dr. P. Sydney Jones. It was also decided to establish a Professorship of Pathology upon the same footing as the recent professorships in the University, and that the necessary steps should be taken to invite applications.

Bendigo Hospital.

Dr. Walter Fowler, late of Echuca, has been appointed medical superintendent of the Bendigo Hospital, Victoria.

Treatment of Sewage.

The Sydney Water and Sewage Board propose to erect a septic tank on the Scott-Moncrieff system for the treatment of sewage at Rose Bay Park—a place of public resort—and also at Balmoral Beach, a place thronged with holiday-makers on Saturdays and Sundays. The proposal has called forth great indignation and protest on the part of the public. The board and its expert officers maintain that the system is quite inoffensive in its operations and has been practically tested at the Botany Bay sewage farm. Dr. Mackellar, M.L.C., and Dr. Norton Manning, late President of the Board of Health, have sent in a report to the local councils concerned, in which they state that the septic tanks now in operation at Botany are very unsatisfactory and cause offence, and while permissible at a sewage farm as an adjunct and at places removed from population should not be erected in places of public resort.

Hospital Saturday in Sydney.

The annual collections on behalf of the Sydney hospitals were held on May 4th and proved very satisfactory, the total amount collected being £4375, a considerable increase on previous years.

Death under Chloroform.

A case of death under chloroform occurred recently at a private hospital at Darlinghurst, Sydney, somewhat exceptional from the circumstances that the victim was an infant, only 10 months old, who suddenly collapsed and the medical evidence at the inquest failed to account for the collapse.

The Medical Practitioners Act in New South Wales.

A case of some importance with reference to prosecutions under the new Medical Act was recently decided by the Full Court of New South Wales A "Chinese doctor" was prosecuted at Queanbeyan under the Act for "using a title implying that he was a legally qualified medical practitioner—to wit, the title of physician." The man's sign read "Chinese physician and surgeon." The magistrates decided in favour of the Chinaman and the Crown appealed against their decision to the Full Court who by a majority, but not unanimously, supported the magistrates' decision on the ground that the original information was wrongly laid under the second instead of the first section of the Act and that the words "Chinese physician and surgeon" did not imply that the man was a legally qualified medical practitioner. Under the first section of the Act it was an offence to use the word "physician" at all, but that was not the charge in this case.

Honours for Australian Practitioners in South Africa.

Surgeon-Captain N. R. Howse of the New South Wales Medical Staff has been gazetted for the Victoria Cross. He formerly practised at Orange, New South Wales. Surgeon-Captain R. Roth, also of the New South Wales Medical Staff, has been created a Companion of the Distinguished Service Order. He was Surgeon-Captain Howse's senior at Vredefort with Ridley's brigade where the action occurred which gained both officers distinction. Surgeon-Captain Howse dashed out in a hail of bullets and brought in a young trumpeter who was wounded.

Death of Dr. Dagnall Clark.

The news of the sudden death of Dr. Charles Alfred Dagnall Clark came as a great shock to the public of Sydney and his many friends. Dr. Clark was at one time physician to the Sydney Hospital and at the time of his death was on the staff of the North Shore Cottage Hospital. He had practised most successfully at North Shore for about 20 years and was held in the greatest respect for his professional skill and great kindness of heart.

June 15th.

Obituary.

GEORGE HANBY DE'ATH, L.R.C.P. LOND., M.R.C.S. ENG.

THE death is announced of this well-known and esteemed practitioner at Buckingham on Sunday, July 7th, from heart failure due to overwork and an attack of gout. The son of the late Robert De'Ath who had practised at Buckingham for many years, he was educated at Westminster and in due time entered at Guy's Hospital where he had a distinguished career as a student. He qualified M.R.C.S. Eng. in 1884 and L.R.C.P. Lond. in 1885 and on his father's early and sudden death in 1886 succeeded to the practice which he carried on with much success, though he was extremely young for so important a post.

At the time of his decease Mr. De'Ath held the appointments of coroner to the Winslow Division of North Bucks, medical officer of health to the borough of Buckingham, medical officer and public vaccinator to the Buckingham Union, and surgeon to the Oddfellows and other societies. The duties attached to these several appointments, as well as a large private practice made severe demands upon his health and strength. He was not one to spare himself in any way, being extremely devoted and conscientious towards his patients and official duties. Hence his early breakdown. He had been confined to his room for a fortnight or so with synovitis in both knees, but no danger to his life was anticipated from this cause, though it was known to himself and others that he had an enfeebled and dilated heart. Indeed, his old friend Dr. J. F. Goodhart had within a few weeks warned him to be careful and to give up his bicycle, to which he was much attached. However, after an attack of syncope on the previous evening he succumbed early on the morning of July 7th in his fortieth year. By a strange coincidence the last inquest which he held (on June 22nd) was in a case of sudden death from heart disease in the cricket field at Winslow.

To those who knew him well Mr. De'Ath was endeared by his large-hearted tolerance of the opinions of others, an unselfish devotion to his family and friends, and a warm and affectionate nature. Highly cultured and well-read, he was a successful practitioner and readily gained the confidence and esteem of his patients. He took part, too, in public affairs with keenness and skill. A politician of somewhat advanced views, he made his influence felt in local matters. He was also an able and eloquent speaker and debater and an excellent amateur actor. Many of these acquirements he learnt when at Westminster, as he was a constant attendant at the debates in the House of Commons and formed many influential friendships amongst public men. Indeed, at that time he was generally known as the "Boy Politician." One of his latest appearances on the platform was to oppose—and very successfully—an anti-vivisectionist lecturer who visited Buckingham last spring and still more recently he joined in the welcome given by the town to the Bucks Yeomen on their return from South Africa. During the occupancy of Stowe by the late Comte de Paris, Mr. De'Ath was the trusted and confidential attendant of the family and household. He was, too, the welcome adviser of many of the best families in his neighbourhood.

A member of the British Medical Association, he filled the office of president of the South Midland Branch in 1896. Mr. De'Ath was the author of works upon cholera, infant feeding, and sanitation, and contributed an interesting paper on Medical Practice which was read before the Physical Society of Guy's Hospital. But his many occupations left him little time for literary work, though he was an extensive reader in all subjects connected with his profession.

A widow and two young sons are left to mourn their loss, besides a host of friends and neighbours to whom he had become almost a necessity. His last illness was soothed by the constant attendance and advice of his partner, Mr. Howard, and his old friend Mr. Herbert Menzies. The funeral took place on July 11th, at the parish church, Buckingham, and was attended by a large number of mourners, including the mayor and corporation of the borough and many old fellow students, patients, and friends. Every mark of respect to his memory was shown by the closing of shops and other tokens of mourning. Kind and affectionate notices of his life and work have appeared in the local papers, fitting memorials of the esteem in which he was held by his fellow townsmen and townswomen.

JOHN EDWIN SCOWCROFT, M.D. ST. AND., F.R.C.S. EDIN., F.F.P. & S. GLASG., J.P.,

MAYOR OF BOLTON.

JOHN EDWIN SCOWCROFT, who was a well-known practitioner in Bolton, died suddenly in the early morning of July 10th, at the age of 56 years. For some years Dr. Scowcroft had taken an active part in municipal matters, and at the time of his death was mayor of the town and an alderman of, and J.P. for, the county borough. He was a member of an old Bolton family and in 1864 became an undergraduate of Durham University. He studied medicine at the Manchester and Liverpool Schools of Medicine, and was prosecter of anatomy at the Royal School of Medicine, Manchester. In 1868 he became a Licentiate of the Royal College of Physicians of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow; commencing practice in Bolton shortly afterwards he succeeded in establishing a large practice. He afterwards became F.F.P. & S. Glasgow, 1872; F.R.C.S. Edin., 1876; and M.D. St. And., 1886. He became honorary surgeon to the Bolton Infirmary and was Surgeon-Captain in the 2nd Volunteer Battalion Loyal North Lancashire Regiment. He continued to discharge the duties of his profession to the last, and being punctilious in his habits got through an enormous amount of work. He was popular as a public man and obtained a warm place in the hearts of the people of Bolton by his kindly consideration of all in the discharge of his municipal and magisterial duties. He had been ailing from time to time from some throat affection, but continued his active work, and on the night of July 9th he had been at his surgery as late as 9.30 P.M. Early in the next morning he was seized with apoplexy and died before Dr. R. Patrick or Dr. A. H. Taylor, his assistant, had time to arrive. He leaves a widow, a son, and a daughter. The son, who is a member of the profession, left a few weeks ago for South Africa. Dr. Scowcroft was interred on July 13th in the churchyard of St. Michael's, Great Lever. The funeral being of a public character there were present a large number of magistrates, members of the corporation, and heads of the different departments, as well as a number of gentlemen representing various societies and institutions.

DEPUTY INSPECTOR-GENERAL RICHARD DOMENICHETTI, M.D. EDIN.,

HONORARY PHYSICIAN TO THE KING.

DR. RICHARD DOMENICHETTI, whose death occurred at his residence, Collingham House, Woodhall Spa, Lincoln, on July 12th, was the eldest son of the late W. L. Domenichetti, of the 95th Regiment. He graduated in medicine at Edinburgh in 1845, serving afterwards in the 8th King's Regiment and 1st Gordon Highlanders (75th Foot) He was appointed to the personal staff of Sir Willoughby Cotton, G C B, and afterwards to the staff of the late Sir H Havelock *Dr Domenichetti* was present as senior medical officer in the actions preceding the capture of Cawnpore and the relief of Lucknow, and received the thanks of the President of the Council of India for his services before Lucknow in 1857, and was awarded the medal and clasp The late Colonel F C Maude in his work "Memories of the Mutiny," alluding to the fact that Havelock's untimely death deprived many officers of the recognition of their services writes as follows —"I am forced to limit my observations to the *personnel* of Havelock's column, and to select from among them the men I have personally known, whose services were the most brilliant, but yet who have received the *minimum* of recognition or reward Foremost among these I would enumerate Delafosse, Dodson, and Domenichetti, the last-named, though a non combatant, was our P M O, and in that capacity was present at every engagement until he was left behind in the Alum Bagh with the sick and wounded, in medical charge of its tiny garrison, under MacIntyre of the 78th Highlanders" Dr Domenichetti after retiring from the service, acted for 25 years as medical officer of health at Louth Lincolnshire In 1895 he was appointed honorary physician to Queen Victoria, and in 1897 was the recipient of the Queen's Jubilee medal

Dr Domenichetti had been in failing health for the last two years In June, 1890 he took up his residence at Woodhall Spa when he was found to be suffering from senile glycosuria His bodily weakness and gradual emaciation had made such progress that he kept to his bed for the last weeks of his illness and he died in a comatose condition at the ripe age of 78 years

THE HOSPITAL FOR EPILEPSY AND PARALYSIS—The annual meeting of the governors and supporters of the Hospital for Epilepsy and Paralysis and other Diseases of the Nervous System was held on June 26th, at the hospital, when the Right Rev the Bishop of Stepney presided. The Chairman in moving the adoption of the report, said that he had heard with deep regret of the present necessity for closing the in patient department, and it seemed a hard case and a deplorable wrong that a hospital capable of doing so much good and having done so much in the past, should meet with such a crisis in its affairs Canon Barker said he felt that the committee were not only to be condoled with but also to be congratulated, seeing that firstly they had secured a site for a projected building and that secondly, after the purchase of the site, they had still in hand a sum of no less than £12,000 He considered that this hospital had done a splendid work, even in a building which was admittedly at best a makeshift and imperfectly adapted for its purpose, and it was now going to have a really beautiful home, where it would be housed in a way difficult to improve upon The report having been unanimously adopted general business was transacted and the meeting terminated with a vote of thanks to the chairman

PRESENTATIONS TO MEDICAL PRACTITIONERS—Mr G Hett M D Edin, M R C S Eng, L S A., was the recipient on July 5th of a silver watch from the members of the Westbourne Provident Medical Dispensary The watch bears the following inscription —"Presented to Dr Hett by *his patients and friends in the Westbourne Provident Medical Dispensary, in acknowledgment of his untiring devotion to this institution for twenty six years*"—Mr F Lynes, M D St And, M R.C S Eng, L S A, J P, on his retirement as surgeon of the Earl of Craven Lodge (M U) of Oddfellows after 37 years of service has received from the officers and brethren a marble clock bearing the inscription 'Earl of Craven Lodge M U Presented by the officers and brethren to Dr E Lynes as a small token of their appreciation of his ability, kindness, and attention during the 37 years he held the position of surgeon to the lodge'—Mr J H Carson L.R.C P, L R C S Edin L.F P S Glasg, of Crumlin Ireland, was presented on July 4th with a purse of sovereigns and a tastefully illuminated album containing the addresses and signatures of subscribers and photographs of places of interest in the district, the occasion being the eve of his departure to take up practice in England—Mr J J Hanly, L.R.C P, L R C S Edin, who is leaving Bath to take up a practice in Alderney, has received from the inhabitants in the neighbourhood of Chewton Mendip, Binegar, and Oakhill an illuminated address, which reads as follows —'To Dr J J Hanly M A, Lancet House, Oakhill Bath Dear Sir,—It is with deep regret we, the undersigned hear that you purpose to leave this neighbourhood During the time you have resided amongst us we have alw [illegible] to your duties [illegible] greatly missed, [illegible] Hanly, and family every success in your new sphere of labour, and trust health and prosperity may attend your footsteps We are, yours very sincerely —A gold bracelet was also presented to Mrs Hanly by the workers and the poor of ten parishes as a token that they had not forgotten the wife of a hard working doctor' Mr Hanly has obtained the Government grant for successful vaccination

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN—A quarterly court of the directors of this society was held on July 10th, at 8 30 P M The chair was taken by the President Mr Christopher Heath Seven new members were elected and the deaths of four members were reported and the election of a member was declared void. Two fresh applications for grants were read from widows, and grants at the rate of £50 a year were made It was resolved that a sum of £1284 should be *distributed* among the 52 widows, 14 orphans and six recipients from the Copeland Fund. The expenses of the quarter amounted to £45 13*s*

THE BRISTOL BOARD OF GUARDIANS AND THE TREATMENT OF PHTHISIS—The Bristol Board of Guardians have been recently discussing the treatment of their phthisical patients, and on June 15th a committee urged the desirability of obtaining a suitable house in the country for the better treatment of the cases of phthisis (at present 34 men and seven women) in their workhouse infirmary At the meeting held on July 11th a report was presented from the hospital committee recommending the provision of a home at Clevedon They suggested a building named "Hallam Hall," which could be fitted up to provide accommodation for 35 male and a similar number of female patients The estimated expenditure was £600 yearly The committee considered that by means of such a home the pressure of the workhouse infirmaries would be relieved, and from information received from the district medical officer an average of about six out-door poor cases could be sent weekly After some discussion the guardians referred the matter back to the committee to reconsider and to report upon as to a lease of the building being arranged for 14 years, including a provision entitling the guardians to purchase at a given price at any time during the term.

BRITISH DENTAL ASSOCIATION. — Mr. J. L. Robertson of Cheltenham being the President-elect, the Central Counties Branch of the British Dental Association held its annual meeting in Cheltenham on July 12th and 13th. At the business meeting the following officers were elected: President for 1902-3, Mr. J. Mountford, L.D.S. Eng. (Birmingham). Vice-Presidents: Mr. A. E. Donagan, M.A. Cantab., L.D.S. Edin. (Birmingham), and A. E. Vickery, L.D.S. Ireland (Coventry). Representative on the Council of the British Dental Association, Mr. H. R. F. Brooks (Banbury). Honorary treasurers: Mr. Malcolm Knott, L.D.S Glasg. (Birmingham), and Mr. G. F. Cale Matthews, L.D.S. Eng (Birmingham). The secretary's report showed that the membership had increased from 66 to 71 in the branch this year.—Mr. Vickery, the retiring president, gave a brief valedictory address at 6.30.—Mr. J. L. Robertson, who was cordially greeted on rising to make his first speech as President, said, in the course of his remarks, that, like their retiring President, he was strongly of opinion that more attention should be devoted to the mechanical department of dentistry. He thought that a good deal of the time that was devoted to surgical science might be more profitably employed in the workshop.—The President afterwards entertained the members and several local friends (including the Mayor of Cheltenham) to dinner at the Queen's Hotel.—On July 13th papers of a technical nature were discussed, and at noon Mr. Robertson invited the members to his house at Withington, where lunch and tea were provided, and the programme included a drive through Lord Eldon's estate to the Roman Villa.

EASTERN COUNTIES ASYLUM FOR IDIOTS. — The annual meeting of the friends and subscribers of the Eastern Counties Asylum for Idiots, which was held at Norwich under the presidency of the Duke of Norfolk, was the occasion of much well-deserved congratulation. In moving the adoption of the annual report the president of the meeting concluded his remarks by alluding to the charity as one of which the eastern counties ought to be proud—a charity in which implicit confidence could be placed and which it was a privilege to be allowed to help. Sir Frederic Bateman, the Mayor of Norwich, the Dean of Norwich, and the sheriff (Mr. Cozens Hardy) were no less complimentary in their comments upon the institution, and the very large number of persons present proved that the expressions of these speakers as to the way in which the charity was administered and managed were no mere exaggerated statements, but really represented a substantial feeling of confidence and determination for future support. Necessity for sanitary reform had involved the asylum in unusual expenses by which a deficit had been incurred. It was satisfactory to hear that this was already made good except for a comparatively small amount which the authorities of the institution appealed with confidence to the public to supply. One of the most satisfactory features of the asylum is the success with which different forms of employment have been adopted for bringing out and developing the least talent or ability that a patient may possess. Some of the work of the feeble-minded inmates of the Eastern Counties Asylum might well be acknowledged with pride even by artificers more fortunately endowed from birth with proper brain development.

THE APPOINTMENT OF POLICE SURGEON AT EXETER.—There has recently been some friction at Exeter between the town council and the police surgeon and the appointment has been advertised. At the meeting of the town council held on July 10th it was reported that there were only two applicants for the post. One of the members stated that he considered that it would be a great mistake if the council made the appointment under the circumstances; they had a gentleman who for many years had discharged the duties to the satisfaction of everyone and now it was proposed to select as his successor one of two gentlemen neither of whom was known to the citizens. Another speaker thought it a reflection on the council that only two candidates had applied and considered that the medical profession had boycotted the council. Eventually one of the two applicants was elected, several members refraining from voting.

A HEALTHY VILLAGE.—The village of Norton-Fitzwarren in Somerset has shown a remarkable freedom from death during the past 12 months, for not one death was registered from June 21st, 1900, to June 24th, 1901. The village has a population of over 600 and the lowest number of deaths that had ever previously occurred in one year was five.

THE HOSPITAL OF ST. JOHN AND ST. ELIZABETH, ST. JOHN'S WOOD.—The Lord Mayor, accompanied by the Lady Mayoress and the Sheriffs of the City of London, paid a visit in full civic state on July 15th to St. John's-wood and opened the new buildings in Grove-end-road of the Hospital of St. John and St. Elizabeth. The civic party were received by the Duke of Norfolk (President of the hospital), Lord Clifford of Chudleigh (chairman of the Board of Management), the Mayor of Marylebone (Mr. Boulnois), and the Mayoress. The hospital, which has been transferred from Great Ormond-street, Bloomsbury, will afford accommodation for 110 in-patients. Lord Clifford of Chudleigh, addressing the Lord Mayor, said that the hospital was founded in 1856 and its object was the reception of patients suffering from incurable or long-standing disease. To support the hospital with its present number of patients an income of about £2000 a year was required, and £1000 a year in addition would enable the hospital to be kept full. In his reply the Lord Mayor referred to the fact that the hospital was open to the afflicted of all shades of religious opinions and he heartily wished it success.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following is the prize list for the summer session, 1901:—Carmichael Scholarship, £15: W. R. Ormsby. Mayne Scholarship, £15: J. P. Byrne. Gold and Silver Medals in Operative Surgery: gold medal. C. W. Ewing; silver medal. A. Charles. Stoney Memorial Gold Medal in Anatomy: R. W. Bukitt. Practical Histology: A. N. Crawford, first prize (£3) and medal; J. S. Sheill, second prize (£1) and certificate. Practical Chemistry: E. J. Clarke, first prize (£3) and medal; J. M. Hayes, second prize (£1) and certificate. Public Health and Forensic Medicine: Miss J. C. Hargrave, first prize (£3) and medal; S. B. Hanbury, second prize (£1) and certificate. Materia Medica: J. S. Sheill, first prize (£3) and medal; J. McQuillan, second prize (£1) and certificate. Practical Pharmacy: Miss C. O'Meara, first prize (£3) and medal; J. M. Alcorn, second prize (£1) and certificate. Biology: R. Bury, first prize (£3) and medal; F. X. Costello, second prize (£1) and certificate. The schools of surgery will resume work after the summer recess on Tuesday, Oct. 1st.

AUGUST BANK HOLIDAY ON THE CONTINENT.—The Great Eastern Railway Company announce that for the convenience of holiday-makers on the continent cheap tickets will be issued to Brussels available for eight days, *viâ* Harwich and Antwerp. Passengers leaving London in the evening are timed to reach Brussels the following morning. Tickets at cheap fares will be issued by the Antwerp route to Berne from July 24th to 27th. For visiting The Hague, Amsterdam, and other parts of Holland, the Rhine, North and South Germany, and Bale for Switzerland, special facilities are offered *viâ* the Great Eastern Railway Company's Royal British Mail Harwich-Hook of Holland route, through carriages being run to Amsterdam, Berlin, Cologne, and Bale. There is a restaurant car on the North and South German express trains to and from the Hook of Holland. The General Steam Navigation Company's fast passenger steamers will leave Harwich for Hamburg on July 31st and August 3rd, returning August 4th and 7th.

VACCINATION NOTICES.—At the meeting of the Pwllheli Board of Guardians held on July 10th, the public vaccinator drew attention to the fact that the vaccination forms were in English and that this rendered them practically useless in the rural districts, and added that in somes places the forms had been mistaken for bills. After some discussion it was decided to request the Local Government Board to supply vaccination notices written in Welsh, and it was further determined to ask all the Welsh boards of guardians to adopt similar resolutions.

THE HEALTH OF CRICCIETH.—At the meeting of the Criccieth Urban District Council held on July 6th the medical officer of health reported that the death-rate for 1900 was 11·8 per 1000, the estimated population being 1700. The council decided to support the scheme of the Carnarvonshire Joint Sanitary Committee to appoint a bacteriologist for one year and so to add to the precautionary measures for the prevention of the spread of infectious diseases.

VACCINATION GRANT.—Mr. W. G. Evans, medical officer of the Second District, Frome Union, has been awarded the Government grant for successful vaccination for the eighth time.

FUNERAL OF SURGEON J. G. CORRY, R.N.—The funeral of Surgeon J. G. Corry, R.N., took place in the Plymouth Cemetery on July 10th with full naval honours. The band of the *Vivid* led the procession, followed by over 100 sailors from the naval barracks. The field carriage, on which was placed the coffin, was drawn by bluejackets. The father of the deceased, Mr. J. Corry of Donegal, was present, and officers from the barracks and ships at Plymouth and Devonport acted as pall-bearers.

THE BRISTOL LIFEBOAT SATURDAY FUND.—At a meeting held on July 10th it was decided that a special effort should be made for the Bristol Lifeboat Saturday Fund, it being pointed out that in the last three years Bristol had contributed £1161 to the funds of the Lifeboat Institution—a decrease of £934 as compared with the previous three years.

MEDICAL MAGISTRATES.—Mr. F. H. Tinker, L.R.C.P. and L.M. Edin., M.R.C.S. Eng., has been placed upon the Commission of the Peace for the County of Cheshire.—Mr. W. Moxon, M.D. Durh., M.R.C.S. Eng., L.R.C.P. Ed., has been placed on the Commission of the Peace for the County of Derby.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Registration of Plumbers.

In the House of Lords a Bill to establish a system of registration for plumbers has been introduced by Lord GLENESK. Obviously at this period of the session its chance of passing into law is slight.

Sale of Intoxicating Liquor to Children.

The Bill to prevent the sale of intoxicating liquor to children is now before the Grand Committee of the House of Commons on Law, where already it has been altered in several important particulars. The limit of age, for instance, has been reduced from 16 to 14 years, and the difficulty with regard to the delivery of liquor has been met by the insertion in the second clause of words exempting from the scope of the proposed legislation delivery at the residence or working place of the purchaser.

Condition of the Concentration Camps.

A committee of ladies is to be appointed by the War Office to go out to South Africa and to inquire into and to report upon the condition of the various concentration camps.

HOUSE OF COMMONS.

THURSDAY, JULY 11TH.

Influenza among Horses.

Mr. HERMON-HODGE asked the [illegible] whether he was aware that an epi[illegible] [illegible] of the horses imported into [illegible] tes of America, he could inform [illegible] at our ports to discover and, if [illegible] ifected animals.—Mr. HANBURY [illegible] the Foreign Office as to the [illegible] New York I have received the following telegram: "Mild and local epizoötic laryngeal influenza prevalent in New York and Brooklyn. Horses for export to United Kingdom which are chiefly drawn from western and middle States appear to be unaffected. All horses are examined before shipment by Government inspectors and as yet none are reported to have been rejected; they are kept in Government stockyards and have little chance of infection." The local authorities at most of the principal ports are [illegible] they arrive. At the Port of [illegible] the information obtained at [illegible] the part of our own officers. [illegible] lepend the question whether [illegible] to require further adminis[illegible]

[illegible]

Mr. WILLIAM REN[illegible] [illegible] would cause a strict inquiry into this case [illegible] plied. I am informed by the police that [illegible] The father applied for a burial order on [illegible] officer did not feel justified in giving the [illegible]

[illegible] of the regiment at Bloemfontein, and the number of deaths; how many of the men were left sick from enteric fever when the regiment left Bloemfontein; and how many died from enteric fever in the two months after the regiment had left.—Mr. BRODRICK replied: The regiment reached Bloemfontein in the week ending April 6th, 1900, and had 19 admissions to hospital for all causes during the march [illegible]

The Hospital Ship "Maine."

Mr. ARNOLD FORSTER announced that it is proposed by the Admiralty to send the hospital ship *Maine* to the Mediterranean at an early date.

FRIDAY, JULY 12TH.

Infectious Diseases Hospital for Wakefield.

Mr. PICKARD asked the President of the Local Government Board [illegible] to the fact that the Wakefield [illegible] Government Board for sanction [illegible] an infectious diseases hospital [illegible] that this site was outside the district of Stanley where there [illegible] at the hospital was proposed to [illegible] stricts of Stanley; and seeing that objection was taken to the erection of the hospital by the inhabitants of Stanley whether before sanctioning the loan he would cause [illegible] there was a suitable site for [illegible] or in places [illegible] where there [illegible] Mr. WALTER [illegible] one of the [illegible] an applica[illegible] the proposed [illegible] ort as to the [illegible] onsideration [illegible]

MONDAY, JULY 15TH.

Burial Scandal at Greenwich.

[illegible] y notice by the [illegible] committee re[illegible] sponsible and the [illegible] urrence of such [illegible] been made to [illegible] to desired that [illegible] he license was [illegible]

TUESDAY, JULY 16TH.

Dental Provision for the Troops.

[illegible] the Secretary of State for War whether [illegible] teeth; whether he could state [illegible] committee which was to report whether the Government, in [illegible] question in time of peace as [illegible] their serious attention?—Mr [illegible]

Death Certification in Scotland.

[illegible] he was aware [illegible] in the registra[illegible] rsons signing a certificate that they were present at the death, when, as a matter of fact, they had been elsewhere, and whether he would be prepared to take such steps as would secure that the law was complied with, and [illegible] ate under [illegible] led; I am [illegible] death, it [illegible] each case [illegible] Mr WASON [illegible] with the information in his possession, inquiry would be made. The LORD ADVOCATE replied that he would pass on the information to the registrar-general, who no doubt would make inquiry.

The Position of Dr W. Scott Tebb at Penge.

When the House was [illegible] the vote for the salaries and expenses of [illegible] in NORTON called attention to the [illegible] Board to sanction the appointment of Dr [illegible] officer of health of Penge, because of his views with regard to vaccination. He claimed that the local authority was quite alive to its responsibilities and that it ought not to be overruled in this way.—Sir MICHAEL FOSTER said that Dr Tebb was one of his pupils and he had a high opinion of his character and ability, but he had read his book on vaccination and he thought that the refusal of the Board to sanction the appointment was perfectly justified He could not conceive how anyone holding the views of Dr. Tebb could be a proper instrument for carrying on the combat against small-pox in this country where vaccination was the legalised method.—Sir Walter Foster said that, in his opinion, the President of the Local Government Board was right when he felt that it would be a very dangerous experiment to appoint as a medical officer of health one who had published opinions strongly criticising the efficiency of vaccination.—Mr. Walter Long said that so long as he was responsible for the Local Government Board no power on earth would induce him to sanction the appointment as a medical officer of health of a man who held the views of Dr. Tebb with regard to vaccination.—Mr. Corrie Grant protested against the action of the r[illegible] pinion Dr. Tebb was being punished for [illegible] views with regard to vaccination, though as a medical officer of health he would have nothing to do with vaccination.—Mr. Walter Long said that a medical officer of health would have a great deal to do with vaccination in the event of his district being invaded by an epidemic of small-pox.—Mr. Corrie Grant said that it was evident that we were passing from the tyranny of the priests to that of the doctors, and he thought that the latter was the greater evil. The local authority was prepared to entrust Dr. Tebb with this work and there was no suggestion that he was unfit for it, and as a protest he would move the reduction of the vote by £100.—Mr. Shipman also protested against the action of the Local Government Board.—On a division being taken the motion to reduce the vote was rejected by a large majority.

THE NEW FACTORY AND WORKSHOP LEGISLATION.

PROCEEDINGS IN THE GRAND COMMITTEE.

The Grand Committee of the House of Commons on Trade is steadily working its way through the clauses of the Bill of the Government to amend the Factory and Workshop Acts. At the meeting of the committee on Thursday, July 11th, several points of special interest to medical men were discussed. They arose chiefly in connexion with Clause 25 which provides for the issue of certificates of fitness by certifying surgeons to children and young persons. Mr. Tennant proposed to insert in this clause the following words—viz.: "For the purpose of determining whether he shall grant such certificates and whether he shall impose such conditions, a certifying surgeon may at any reasonable time enter, inspect, and examine any factory or workshop within his district and any part thereof, and may observe any process which is carried on in the factory or workshop, and any person who delays or obstructs a certifying surgeon in the exercise of this power shall be liable to a fine not exceeding £5." The hon. Member expressed the opinion that in a matter of this kind the certifying surgeon should have the same power as the Home Office inspector, and that any person who delayed or obstructed the former should be liable to a penalty.—Mr. Ritchie, the Minister in charge of the Bill, thought that the proposal of the hon. Member went too far, but said he would be prepared to insert in the clause these words: "A certifying surgeon shall have the same powers as an inspector for the purpose of examining any process in which a child or young person presented to him for the granting of a certificate is proposed to be employed."—Mr. Tomlinson insisted that a certifying surgeon, however well equipped he might be for the work of his profession, could not reasonably be expected to have the knowledge necessary to enable him to decide whether or not a particular process of manufacture was suitable for the employment of a child or young person.—Mr. Tennant asked the Home Secretary whether he would not make provision for a penalty.—Mr. Ritchie replied that he did not think such provision was necessary because the certifying surgeon could always withhold his certificate.—Mr. Tennant withdrew his amendment and the Committee accepted the words offered by Mr. Ritchie.—Mr. Tennant then proposed to insert in the clause these words—namely, "A certifying surgeon shall not examine any person for the purpose of a certificate of fitness for employment unless adequate means of privacy are provided for the examination."—Mr. Ritchie thought that it would be a mistake to lay down a regulation of this minute character and Mr. Tennant did not press his amendment.—Mr. Tennant next moved an amendment requiring certificates of fitness for workshops as well as for factories. He said that many representations had been made to him by certifying surgeons and others to the effect that the health of children and young persons was undermined by employment of an unsuitable nature in workshops. In experience it was found that a child or young person might be refused a certificate for employment in a factory and then went to a workshop and obtained employment there.—Mr. Ritchie said that the position of the law at present was that no certificate of fitness was required by law in the case of a workshop, but there was a power on the part of the Secretary of State to order that in any class of workshop where he considered it requisite a certificate should be required. The reason for the distinction between a factory and a workshop was perfectly clear. A factory, as a rule, was a place where machinery of various kinds, some of it dangerous, was in use. In a workshop this condition did not arise, and many workshops were extremely small. On the whole he did not think it necessary to extend the existing law.—Mr. Tennant said that he was disappointed with this answer. If a girl got employment in a clothing factory her machine was worked by power; if she went into a dressmaker's workshop she had to turn the machine with her foot, and everybody knew that the very worst class of sweating went on in dressmakers' shops. He did not see, therefore, why a certificate of fitness should be required in the one case and not in the other.—On a division the proposal of Mr. Tennant was rejected by 28 to 25 votes.—The Home Secretary agreed to accept an amendment in the name of Mr. Tennant repealing the paragraph in the principal Act which provides that the occupier of the factory may deduct the certifying surgeon's fee or part of it from the wages of the person for whom the certificate is granted.—Sir James Rankin asked the Home Secretary whether under this clause the certifying surgeon would be entitled to examine a secret process of manufacture.—Mr. Ritchie replied that he would only have power to inspect the process in which it was proposed to employ the child or young person and that consequently the matter would rest entirely in the hands of the employer.

At a later stage in the proceedings Clause 28, dealing with bakehouses, was discussed. This clause proposes that after Jan. 1st, 1904, an underground bakehouse shall not be used unless certified by the district council to be suitable for that purpose, and that an underground bakehouse shall mean a bakehouse any room of which is so situate that the surface of the floor is more than three feet below the surface of the footway of the adjoining street or of the ground adjoining or nearest to the room.—Mr. Renshaw said that some people had come to the conclusion that under this clause all bakehouses three feet below the surface of the roadway would be disallowed.—Mr. Ritchie explained that this was not the case. Such bakehouses would not be prohibited if a certificate were got from the local authority. Of course, the clause only referred to old bakehouses; new ones were provided for by the existing law. There was a great scandal in connexion with these old underground bakehouses and he thought that they should not be allowed to go on for all time. While he said this he was prepared to extend the allowance of time to Jan. 1st, 1906, instead of Jan. 1st, 1904, as proposed in the clause.—Mr. John Burns urged the Home Secretary not to make this concession and quoted articles in The Lancet and other journals as to the present deplorable state of things. He thought that their owners had had sufficient notice of the intention and desire of the legislature to put a stop to these unhealthy and unsuitable bakehouses.—Sir Henry Fowler and other members of the Committee spoke in support of Mr. Burns and Mr. Ritchie announced that he would stand by the date in the clause. An amendment to change the definition of an underground bakehouse to a place the ceiling of which was less than six feet above the surface of the roadway was rejected by the Committee by a large majority.

The Grand Committee met again on Monday, July 15th, and made substantial progress with the Bill. There was some further discussion on the underground bakehouse clause.—Mr. Parkes moved to insert in the clause a provision that no certificate shall be refused by a district council where the underground bakehouse complies with the existing Acts of Parliament regulating underground bakehouses.—Mr. Ritchie, in opposing this amendment, said that the existing Acts were not enough, for it was notorious that baking was carried on in premises which were wholly unsuitable.—Captain Jessel thought that a slur had been cast upon the local authorities in London, many of whom had been very energetic in enforcing the law and securing a better state of things in bakehouses.—Sir John Stirling-Maxwell suggested that if an appeal from the decision of the district council were given the case would be sufficiently met.—Mr. Ritchie said that he was prepared to give an appeal to a court of summary jurisdiction.—The amendment was thereupon withdrawn and words were inserted in the clause providing for an appeal in the case of a refusal of a certificate to a court of summary jurisdiction. The clauses dealing with humidity and temperature were passed by the Committee practically without alteration. Clause 31 provides that in any factory or workshop where lead, arsenic, or other dangerous substance is used a person shall not be allowed to take a meal or to remain during the times allowed for meals in any room in which any such substance is used and suitable provision shall be made for enabling the persons employed in such rooms to take their meals elsewhere in the factory or workshop.—Mr. Seton-Karr thought that this clause imposed unnecessary restriction and expense upon employers and moved to alter the clause so as to read "where preparations of lead are manipulated." He also suggested to the Home Secretary that it should be made a punishable offence for an employé to eat anything in a place where preparations of lead were manipulated.—Mr. Ritchie explained that the wording of the clause had been taken from the Act of 1895, and to alter it would only introduce confusion in interpretation. The intention of the clause was that these matters must not be present in any factory in anything like a dangerous condition and if they were then the meals must be taken outside. Of course if the words were interpreted in their literal sense it would be impossible for a person to take a meal in a room where a window was being inserted in a leaden frame. No court would so interpret the law. He did not wish to see the clause altered, but preferable words to those proposed by the hon. Member would be "used so as to be a source of danger to health."—Mr. Tennant urged the Home Secretary not to accept either form of words.—Mr. Seton-Karr withdrew his amendment and moved to insert the words mentioned by the Home Secretary. After a long debate the Committee rejected the words by a large majority. The clause consequently remained unaltered.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

Andrews, W. H., L.R.C.P. & S.Edin., L.F.P.S.Glasg., has been appointed Medical Officer for the Fourth District Kingsbridge (Devon) Union, vice H. Osborne Grenfell, resigned.

Cargill, L. Vernon, F.R.C.S.Eng., L.R.C.P.Lond., L.S.A., has been appointed Surgeon to the Royal Eye Hospital, Southwark.

Dunlea, M. P., M.D. R.U.I., has been appointed Certifying Surgeon for the Riverstown District in the County of Cork.

Fagan, P. J., L.R.C.P. Irel., has been appointed Lecturer on Elementary Physics in the Catholic University Medical School, Dublin.

Groves, W. G., M.R.C.S. Eng., L.S.A., has been re-appointed Medical Officer of Health of Woodburn Urban Sanitary District.

Hamilton, W. M., M.D. R.U.I., has been appointed Medical Officer of Health of Eccles Municipal Borough.

Harris, J. H., M.R.C.S Eng., L.S.A., has been re-appointed Medical Officer of Dartmouth (Devon) Urban Sanitary District.

Hayes, W. B., M.D. R.U.I., has been appointed Certifying Surgeon for the Union of Tralee, in the county of Kerry.

Hayman, F. D., M.R.C.S. Eng., has been appointed Medical Officer of Health of Ararat, Victoria.

Hogg, J. A., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Medical Officer of Health of Shardlow Rural Sanitary District.

Kelly, C., M.D. Lond., has been re-appointed Medical Officer of Health of West S[illegible] District.

Notes, Short Comments, and Answers to Correspondents.

GOVERNMENT DEPARTMENTS AND MEDICAL CERTIFICATES.

To the Editors of THE LANCET.

SIRS,—I should be obliged for your advice on the following. I was attending a postman, X, as a private patient and I had no connexion, official or otherwise, with the Post Office After the man had been ill a few days the postmaster here said that the Post Office required a medical certificate of the man's state, and asked me to furnish one. I sent him the required certificate. A month or two later he asked me if the man would be able to resume his work, and I informed him that he would be permanently disabled. He then said that the Post Office required a medical certificate to that effect so that they might appoint a permanent postman instead of a substitute, and asked me to give him one. I sent him the required certificate. At no time was any reference made to the patient—i e., that he should supply the certificate—nor was the patient consulted about the certificates, though I subsequently mentioned to him that I had so certified. On July 1st I sent the postmaster here a bill for 10s. 6d. for the two certificates and asked him to forward it to the proper quarter. He to day returned my bill with a curt note that "I am instructed to inform you that X has no claim on the Post Office Department." I made the bill out to the Postmaster General. Is my bill a fair one? and is the amount due by, and recoverable from, the Postmaster-General? I do not claim the amount from the patient X. An answer in your columns will oblige.

I am, Sirs, yours faithfully,

July 11th, 1901. H. P. A.

⁂ We cannot undertake to give legal advice nor could a lawyer do so without fuller details as to the precise circumstances attending each of the two requests for a certificate. All such cases if they are brought into courts of law depend upon the several facts proved with regard to them and no two cases are alike. Speaking from H. P. A.'s letter we do not see that he has much to complain of on general grounds as to the first certificate, at any rate. An employé desiring to be excused from work can hardly expect his employer to pay for the medical certificate which obtains him leave to be absent. It is, however, important in all cases where doubt may arise that the medical practitioner should ascertain definitely beforehand who will be liable to repay him for his services. The making of the necessary inquiry or the stating of the conditions upon which he will act cannot be more disagreeable than having to enter into a discussion, and possibly litigation, afterwards —ED L.

THE PRINTER AGAIN.

OUR esteemed contemporary, the *Journal of the American Medical Association*, in its issue of July 6th, 1901, has on its contents page under the heading "Addresses," the following startling title, "Poverty and Pregnancy. their Cause, Prevention, and Cure." That poor people do sometimes attempt by various measures, some of which are unpleasant, some of which are injudicious, and some of which are illegal, to escape the responsibilities while enjoying the privileges of matrimony is well known But it is so contrary to the medical view of what is right publicly to advocate the prevention of pregnancy as a cure of poverty that we turned to the article with apprehension. Yet we might have guessed to whose jocosity we had fallen a victim. It was the merry printer. Within the pages of the journal the article receives its proper heading—viz , "Poverty and Degeneracy: their Cause, Prevention and Cure."

DUTCH WOMEN AND CHILDREN FUND, VICTORIA LEAGUE.

To the Editors of THE LANCET.

SIRS,—At the invitation of the Victoria League a committee has been formed of a number of well known ladies and gentlemen of both political parties who have joined together to give their help for the relief of the sick women and children in the Boer concentration camps. The committee has been appointed with the full approval of the Secretary of State for War.

The aims of the committee are purely philanthropic, absolutely non-political. There is at present undoubtedly much sickness in the Boer concentration camps, particularly amongst the women and children. The British officers in charge of the camps and their civilian assistants, under difficult conditions, are doing their utmost for the people under their care, but the numbers with which they have to deal are large and some suffering is unavoidable. If by well directed private effort extra comforts and clothing could be distributed to those women and children who are most in want much of this suffering might be prevented. It is thoroughly appreciated by the Government that there is in the concentration camps considerable scope for the exercise of properly regulated private charity, and ladies are now being appointed by the War Office who will visit the camps and will give their help in the distribution of gifts from private sources. A considerable sum has already been subscribed, but much more is needed. The committee of the "Dutch Women and Children Fund" is therefore obliged to call on the generosity of the British people, and it confidently appeals to men and women of all opinions to give their help liberally to this work of pacification, of simple charity and humanity. Pecuniary help will be most useful and the most appreciated. All cheques should be sent to Miss Talbot, Honorary Treasurer, Dutch Wom[illegible] League, Dacre House, Victoria street, S [illegible] "Dutch Women and Children Fund," [illegible] minster Bar [illegible] clothing or [illegible] merchants [illegible] clothing, [illegible] received. A memorandum of directions, as a guide to those who wish to make gifts in kind, is being circulated. All packages intended for "The Dutch Women and Children Fund" should be sent, carriage paid, to Messrs. Barnes and Co, Limited, Battle Bridge-lane, Tooley street, S.E, who have kindly consented to act as agents and shippers to the committee. All communications and inquiries should be addressed to the Honorary Secretary.

I am, Sirs, yours faithfully,
G. BONHAM CARTER, Honorary Secretary.

Dutch Women and Children Fund, Victoria League,
Dacre House, Victoria-street, S.W., July 13th, 1901.

⁂ Pressure on our space compels us to omit the names of the members of the committee.—ED. L.

THE WEIR-MITCHELL TREATMENT.

To the Editors of THE LANCET.

SIRS,—I shall feel much obliged to any of your readers for information respecting either a private home or an institution where a little girl, aged eight years, can be received for treatment mainly upon the lines of the Weir Mitchell plan? The parents are in a position to pay a fair remuneration but not very high charges.

I am, Sirs, yours faithfully,

July 15th, 1901. SPES.

NOTE ON LARGE FŒTUS.

To the Editors of THE LANCET.

SIRS,—On the 4th of this month I delivered Mrs. —— of a male child weighing 16 pounds. It was of the length and size of a child six or seven months old. Owing to the difficulty in extracting the shoulders it was stillborn.—I am, Sirs, yours faithfully,

J. MCCONNELL, M B R.U.I., M.R C S. Eng

Battersea rise, S W., July 9th, 1901.

"THE FREAKS OF MEMORY."

To the Editors of THE LANCET.

SIRS,—In reply to your correspondent A Pariss in THE LANCET of July 13th, p. 116, I think he will find similar cases to substantiate the very interesting one he quotes recorded in the late Professor Sir T. Grainger Stewart's book on Nervous Diseases.

I am, Sirs, yours faithfully,
JOHN ROBERT WILLIAMS, M B. Edin.

Penmaenmawr, July 14th, 1901.

A NEW ADHESIVE TAPE PLASTER.

WE have received from the St. Helens Cable Co. a sample of a new rubber tape which is prepared by coating one side of a sheet of previously vulcanized rubber with a facing of pure Para rubber. The pure rubber remains very adhesive, and the tape if wrapped round the finger or over any bandage or dressing forms a perfectly water-tight covering. It is sold at 5s 6d. per lb.

GERMAN HEALTH RESORTS.

To the Editors of THE LANCET.

SIRS,—Can any of your readers oblige me by informing me of the best route either to Nordrach or Nauheim, or both places, with the cost of journey for two medical men? I wish to combine the pleasure of a holiday with the profit of a personal visit to the sanatoria for consumption and heart disease. I am, Sirs, yours faithfully,

Kent, July 16th, 1901. VIATOR.

R. K.—If our correspondent inquires of his usual medical attendant he will obtain the information which he desires.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND, IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS not used.

BRITISH MEDICAL ASSOCIATION MEETING AT CHELTENHAM.

DURING the forthcoming meeting of the British Medical Association at Cheltenham the representatives of THE LANCET can be consulted at the Queen's Hotel with regard to our reports of papers and proceedings.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol I of 1901, which was completed with the issue of June 29th, and the Title-page to the Volume, were given in THE LANCET of July 6th.

VOLUMES AND CASES

VOLUMES for the first half of the year 1901 are now ready. Bound in cloth, gilt lettered, price 18*s*, carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s*, by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.			
One Year	£1	12	6
Six Months...	0	16	3
Three Months	0	8	2

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates on this or any other ground should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND

During the week marked copies of the following newspapers have been received:—*Yorkshire Post, Mining Journal, Public Health, Liverpool Daily Post, Leeds Mercury, Reading Mercury, Windsor and Eton Express, South African News, Hertfordshire Mercury, Surrey Advertiser, Bristol Mercury, Shepton Mallet Journal, &c*

Terms for Position Pages and Serial Insertions on application.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

An Address

ON

THE COMBATING OF TUBERCULOSIS IN THE LIGHT OF THE EXPERIENCE THAT HAS BEEN GAINED IN THE SUCCESSFUL COMBATING OF OTHER INFECTIOUS DISEASES.

Delivered at the Second General Meeting of the British Congress on Tuberculosis on July 23rd,

BY GEH.-MED.-RATH PROFESSOR DR. ROBERT KOCH,

DIRECTOR OF THE INSTITUTION FOR INFECTIOUS DISEASES, BERLIN, AND MEMBER OF THE IMPERIAL SANITARY BOARD.

THE task with which this Congress will have to busy itself is one of the most difficult, but it is also one in which labour is most sure of its reward. I need not point again to the innumerable victims tuberculosis annually claims in all countries, nor to the boundless misery it brings on the families it attacks. You all know that there is no disease which inflicts such deep wounds on mankind as this. All the greater, however, would be the general joy and satisfaction if the efforts that are being made to rid mankind of this enemy, which consumes its inmost marrow, were crowned with success. There are many, indeed, who doubt the possibility of successfully combating this disease, which has existed for thousands of years and has spread all over the world. This is by no means my opinion. This is a conflict into which we may enter with a surely-founded prospect of success, and I will tell you the reasons on which I base this conviction. Only a few decades ago the real nature of tuberculosis was unknown to us; it was regarded as a consequence, as the expression, so to speak, of social misery, and as this supposed cause could not be got rid of by simple means people relied on the probable gradual improvement of social conditions and did nothing. All this is altered now. We know that social misery does indeed go far to foster tuberculosis, but the real cause of the disease is a parasite—that is, a visible and palpable enemy which we can pursue and annihilate just as we can pursue and annihilate other parasitic enemies of mankind.

Strictly speaking, the fact that tuberculosis is a preventable disease ought to have become clear as soon as the tubercle bacillus was discovered and the properties of this parasite and the manner of its transmission became known. I may add that I, for my part, was aware of the full significance of this discovery from the first, and so will everybody have been who had convinced himself of the causal relation between tuberculosis and the tubercle bacillus. But the strength of a small number of medical men was inadequate to the conflict with a disease so deeply rooted in our habits and customs. Such a conflict requires the coöperation of many, if possible of all, medical men, shoulder to shoulder with the State and the whole population, and now the moment when such coöperation is possible seems to have come. I suppose there is hardly any medical man now who denies the parasitic nature of tuberculosis, and among the non-medical public, too, the knowledge of the nature of the disease has been widely propagated. Another favourable circumstance is that success has recently been achieved in the combating of several parasitic diseases and that we have learned from these examples how the conflict with pestilences is to be carried on. The most important lesson we have learned from the said experience is that it is a great blunder to treat pestilences according to a general scheme. This was done in former times. No matter whether the pestilence in question was cholera, plague, or leprosy, isolation, quarantine, useless disinfection were always resorted to. But now we know that every disease must be treated according to its own special individuality and that the measures to be taken against it must be most accurately adapted to its special nature, to its etiology. We are entitled to hope for success in combating tuberculosis only if we keep this lesson constantly in view. As so extremely much depends just on this point I shall take the liberty to illustrate it by several examples.

The pestilence which is at this moment in the foreground of interest, the bubonic plague, may be instructive to us in several respects. People used to act upon the conviction that a plague patient was in the highest degree a centre of infection, and that the disease was transmitted only by plague patients and their belongings. Even the most recent international agreements are based on this conviction. Although, as compared with formerly, we now have the great advantage that we can, with the aid of the microscope and of experiments on animals, recognise every case of plague with absolute certainty, and although the prescribed inspection of ships, quarantine, the isolation of patients, the disinfection of infected dwellings and ships, are carried out with the utmost care, the plague has, nevertheless, been transmitted everywhere, and has in not a few places assumed grave dimensions. Why this has happened we know very well, owing to the experience quite recently gained as to the manner in which the plague is transmitted. It has been discovered that only those plague patients who suffer from plague-pneumonia—a condition which is fortunately infrequent—are centres of infection, and that the real transmitters of the plague are the rats. There is no longer any doubt that in by far the majority of the cases in which the plague has been transmitted by ocean traffic the transmission took place by means of plague among the ship rats. It has also been found that wherever the rats were intentionally or unintentionally exterminated the plague rapidly disappeared; whereas at other places where too little attention had been paid to the rat plague the pestilence continued. This connexion between the human plague and the rat plague was totally unknown before, so that no blame attaches to those who devised the measures now in force against the plague if the said measures have proved unavailing. It is high time, however, that this enlarged knowledge of the etiology of the plague should be utilised in international as well as in other traffic. As the human plague is so dependent on the rat plague it is intelligible that protective inoculation and the application of antitoxic serum have had so little effect. A certain number of human beings may have been saved from the disease by that, but the general spread of the pestilence has not been hindered in the least.

With cholera the case is essentially different; it may under certain circumstances be transmitted directly from human beings to other human beings, but its main and most dangerous propagator is water, and therefore in the combating of cholera water is the first thing to be considered. In Germany, where this principle has been acted on, we have succeeded for four years in regularly exterminating the pestilence (which was introduced again and again from the infected neighbouring countries) without any obstruction of traffic.

Hydrophobia, too, is not void of instruction for us. Against this disease the so-called protective inoculation proper has proved eminently effective as a means of preventing the outbreak of the disease in persons already infected, but of course such a measure can do nothing to prevent infection itself. The only real way of combating this pestilence is by compulsory muzzling. In this matter also we have had the most satisfactory experience in Germany, but have at the same time seen that the total extermination of the pestilence can be achieved only by international measures, because hydrophobia, which can be very easily and rapidly suppressed, is always introduced again year after year from the neighbouring countries.

Permit me to mention only one other disease, because it is etiologically very closely akin to tuberculosis, and we can learn not a little for the furtherance of our aims from its successful combating. I mean leprosy. It is caused by a parasite which greatly resembles the tubercle bacillus. Just like tuberculosis, it does not break out till long after infection and its course is almost slower. It is transmitted only from person to person, but only when they come into close contact, as in small dwellings and bedrooms. In this disease, accordingly, immediate transmission plays the main part; transmission by animals, water, or the like is out of the question. The combative measures, accordingly, must be directed against this close intercourse between the sick and the healthy. The only way to prevent this intercourse is to isolate the patients. This was most rigorously done in the Middle Ages by means of numerous leper-houses, and the consequence was that leprosy, which had spread to an alarming extent, was completely stamped out in Central

Europe. The same method has been adopted quite recently in Norway, where the segregation of lepers has been ordered by a special law. But it is extremely interesting to see how this law is carried out. It has been found that it is not at all necessary to execute it strictly, for the segregation of only the worst cases, and even of only a part of these, sufficed to produce a diminution of leprosy. Only so many infectious cases had to be sent to the leper-houses that the number of fresh cases kept regularly diminishing from year to year. Consequently the stamping-out of the disease has lasted much longer than it would have lasted if every leper had been inexorably consigned to a leper-house, as in the Middle Ages, but in this way, too, the same purpose is gained, slowly indeed, but without any harshness.

These examples may suffice to show what I am driving at, which is to point out that in combating pestilences we must strike the root of the evil and must not squander force in subordinate ineffective measures. Now the question is whether what has hitherto been done and what is about to be done against tuberculosis really strikes the root of tuberculosis so that it must sooner or later die. In order to answer this question it is necessary first and foremost to inquire how infection takes place in tuberculosis. Of course, I presuppose that we understand by tuberculosis only those morbid conditions which are caused by the tubercle bacillus In by far the majority of cases of tuberculosis the disease has its seat in the lungs, and has also begun there. From this fact it is justly concluded that the germs of the disease—i.e., the tubercle bacilli—must have got into the lungs by inhalation. As to the question where the inhaled tubercle bacilli have come from, there is also no doubt. On the contrary, we know with certainty that they get into the air with the sputum of consumptive patients. This sputum, especially in advanced stages of the disease, almost always contains tubercle bacilli, sometimes in incredible quantities By coughing and even speaking it is flung into the air in little drops—i.e., in a moist condition—and can at once infect persons who happen to be near the coughers. But then it may also be pulverised when dry, in the linen or on the floor for instance, and get into the air in the form of dust. In this manner a complete circle, a so-called *circulus vitiosus*, has been formed for the process of infection from the diseased lung, which produces phlegm and pus containing tubercle bacilli, to the formation of moist and dry particles (which in virtue of their smallness can keep floating a good while in the air), and finally to new infection if particles penetrate with the air into a healthy lung and originate the disease anew. But the tubercle bacilli may get to other organs of the body in the same way and thus originate other forms of tuberculosis. This, however, is a considerably rarer case. The sputum of consumptive people, then, is to be regarded as the main source of the infection of tuberculosis. On this point, I suppose, all are agreed. The question now arises whether there are not other sources, too, copious enough to demand consideration in the combating of tuberculosis.

Great importance used to be attached to the hereditary transmission of tuberculosis Now, however, it has been demonstrated by thorough investigation that though hereditary tuberculosis is not absolutely non-existent it is nevertheless extremely rare, and we are at liberty in considering our practical measures to leave this form of origination entirely out of account. But another possibility of tuberculous infection exists, as is generally assumed, in the transmission of the germs of the disease from tuberculous animals to man. This manner of infection is generally regarded nowadays as proved and as so frequent that it is even looked upon by not a few as the most important, and the most rigorous measures are demanded against it. In this Congress also the discussion of the danger with which the tuberculosis of animals threatens man will play an important part. Now, as my investigations have led me to form an opinion deviating from that which is generally accepted, I beg your permission, in consideration of the great importance of this question, to discuss it a little more thoroughly.

Genuine tuberculosis has hitherto been observed in almost all domestic animals, and most frequently in poultry and cattle. The tuberculosis of poultry, however, differs so much from human tuberculosis that we may leave it out of account as a possible source of infection for man. So, strictly speaking, the only kind of tuberculosis remaining to be considered is the tuberculosis of cattle which, if really transferable to man, would indeed have frequent opportunities of infecting human beings through the drinking of the milk and the eating of the flesh of diseased animals. Even in my first circumstantial publication on the etiology of tuberculosis I expressed myself regarding the identity of human tuberculosis and bovine tuberculosis with reserve. Proved facts which would have enabled me sharply to distinguish these two forms of the disease were not then at my disposal, but sure proofs of their absolute identity were equally undiscoverable, and I therefore had to leave this question undecided. In order to decide it I have repeatedly resumed the investigations relating to it, but so long as I experimented on small animals, such as rabbits and guinea pigs, I failed to arrive at any satisfactory result, though indications which rendered the difference of the two forms of tuberculosis probable were not wanting. Not till the complaisance of the Ministry of Agriculture enabled me to experiment on cattle, the only animals really suitable for these investigations, did I arrive at absolutely conclusive results. Of the experiments which I have carried out during the last two years along with Professor Schütz of the Veterinary College in Berlin I will tell you briefly some of the most important.

A number of young cattle which had stood the tuberculin test, and might therefore be regarded as free from tuberculosis, were infected in various ways with tubercle bacilli taken from cases of human tuberculosis; some of them got the tuberculous sputum of consumptive patients direct In some cases the tubercle bacillus or the sputum was injected under the skin, in others into the peritoneal cavity, in other into the jugular vein. Six animals were fed with tuberculous sputum almost daily for seven or eight months; four repeatedly inhaled great quantities of bacilli, which were distributed in water and scattered with it in the form of spray. None of these cattle (there were 19 of them) showed any symptoms of disease and they gained considerably in weight. From six to eight months after the beginning of the experiments they were killed. In their internal organs not a trace of tuberculosis was found. Only at the places where the injections had been made small suppurative foci had formed, in which few tubercle bacilli could be found. This is exactly what is found when dead tubercle bacilli are injected under the skin of animals liable to contagion. So the animals we experimented on were affected by the living bacilli of human tuberculosis exactly as they would have been by dead ones; they were absolutely insusceptible to them. The result was utterly different, however, when the same experiment was made on cattle free from tuberculosis with tubercle bacilli that came from the lungs of an animal suffering from bovine tuberculosis. After an incubation-period of about a week the severest tuberculous disorders of the internal organs broke out in all the infected animals. It was all one whether the infecting matter had been injected only under the skin or into the peritoneal cavity or the vascular system. High fever set in and the animals became weak and lean; some of them died after from one and a half to two months; others were killed in a miserably sick condition after three months. After death extensive tuberculous infiltrations were found at the place where the injections had been made and in the neighbouring lymphatic glands, and also far-advanced alterations of the internal organs, especially of the lungs and the spleen. In the cases in which the injection had been made into the peritoneal cavity the tuberculous growths which are so characteristic of bovine tuberculosis were found on the omentum and peritoneum. In short, the cattle proved just as susceptible to infection by the bacillus of bovine tuberculosis as they had proved insusceptible to infection by the bacillus of human tuberculosis. I wish only to add that preparations of the organs of the cattle which were artificially infected with bovine tuberculosis in these experiments are exhibited in the museum of pathology and bacteriology.

An almost equally striking distinction between human and bovine tuberculosis was brought to light by a feeding experiment with swine. Six young swine were fed daily for three months with the tuberculous sputum of consumptive patients. Six other swine received bacilli of bovine tuberculosis with their food daily for the same period. The animals that were fed with sputum remained healthy and grew lustily, whereas those that were fed with the bacilli of bovine tuberculosis soon became sickly, were stunted in their growth, and half of them died. After three and a half months the surviving swine were all killed and examined. Among the animals that had been fed with sputum no trace of tuberculosis was found, except here and there little nodules in the lymphatic glands of the neck and in one case a few grey nodules in the lungs The animals, on the other hand, which had eaten bacilli of bovine tuberculosis had without exception (just as in the cattle experiment) severe tuberculous diseases, especially tuberculous infiltration of the greatly enlarged lymphatic glands of the neck and of the mesenteric glands, and also extensive tuberculosis of the lungs and the spleen

The difference between human and bovine tuberculosis appeared not less strikingly in a similar experiment with asses sheep and goats, into whose vascular systems the two kinds of tubercle bacilli were injected

Our experiments I must add are not the only ones that have led to this result If one studies the older literature of the subject, and collates the reports of the numerous experiments that were made in former times by Chauveau, Günther and Harms, Bollinger and others who fed calves swine and goats with tuberculous material one finds that the animals that were fed with the milk and pieces of the lungs of tuberculous cattle always fell ill of tuberculosis, whereas those that were fed with human material did not. Comparative investigations regarding human and bovine tuberculosis have been made very recently in North America by Smith, Dinwiddie, Frothingham and Repp, and their result agreed with that of ours The unambiguous and absolutely conclusive result of our experiments is due to the fact that we chose methods of infection which excluded all sources of error, and carefully avoided everything connected with the stalling feeding, and tending of the animals that might have a disturbing effect on the experiments Considering all these facts, I feel justified in maintaining that human tuberculosis differs from bovine and cannot be transmitted to cattle It seems to me very desirable however, that these experiments should be repeated elsewhere in order that all doubt as to the correctness of my assertion may be removed I wish only to add that, owing to the great importance of this matter, our Government has resolved to appointment a commission to make further inquiries on the subject

But, now, how is it with the susceptibility of man to bovine tuberculosis? This question is far more important to us than that of the susceptibility of cattle to human tuberculosis highly important as that is too It is impossible to give this question a direct answer, because, of course the of it with human beings is out of however, we can try to approach the milk and butter consumed in great cities very often contain large quantities of the bacilli of bovine tuberculosis in a living condition, as the numerous infection experiments with such dairy products on animals have proved. Most of the inhabitants of such cities daily consume such living and perfectly virulent bacilli of bovine tuberculosis, and unintentionally carry out the experiment which we are not at liberty to make If the bacilli of bovine tuberculosis were able to infect human beings, many cases of tuberculosis caused by the consumption of alimenta containing tubercle bacilli could not but occur among the inhabitants of great cities especially the children. And most medical men believe that this is actually the case In reality, however, it is not so That a case of tuberculosis has been caused by alimenta can be assumed with certainty only when the intestine suffers first—i.e., when a so-called primary tuberculosis of the intestines is found. But such cases are extremely rare Among many cases of tuberculosis examined after death I myself remember having seen primary tuberculosis of the intestine only twice Among the great post-mortem material of the Charité Hospital in Berlin 10 cases of primary tuberculosis of the intestine occurred in five years Among 933 cases of tuberculosis in children at the Emperor Frederick's Hospital for Children Baginsky never found tuberculosis of the intestine without simultaneous disease of the lungs and the bronchial glands. Among 3104 post-mortem examinations of tuberculous children Biedert observed only 16 cases of primary tuberculosis of the intestine. I could cite from the literature of the subject many more statistics of the same kind, all indubitably showing that primary tuberculosis of the intestine, especially among children, is a comparatively rare disease, and of the few cases that have been enumerated it is by no means certain that they were due to infection by bovine tuberculosis It is just as likely that they were caused by the widely propagated bacilli of human tuberculosis, which may have got into the digestive canal in some way or other—for instance by swallowing saliva of the mouth Hitherto nobody could decide with certainty in such a case whether the tuberculosis of the intestine was of human or of animal origin Now we can diagnose the two All that is necessary is to cultivate in pure culture the tubercle bacilli found in the tuberculous material and to ascertain whether they belong to bovine tuberculosis by inoculating cattle with them For this purpose I recommend subcutaneous injection which yields quite specially characteristic and convincing results For half a year past I have occupied myself with such investigations, but owing to the rareness of the disease in question the number of the cases which I have been able to investigate is but small What has hitherto resulted from this investigation does not speak for the assumption that bovine tuberculosis occurs in man

Though the important question whether man is susceptible to bovine tuberculosis at all is not yet absolutely decided, and will not admit of absolute decision to-day or to morrow, one is nevertheless already at liberty to say that, if such a susceptibility really exists, the infection of human beings is but a very rare occurrence I should estimate the extent of infection by the milk and flesh of tuberculous cattle and the butter made of their milk as hardly greater than that of hereditary transmission, and I therefore do not deem it advisable to take any measures against it So the only main source of the infection of tuberculosis is the sputum of consumptive patients and the measures for the combating of tuberculosis must aim at the prevention of the dangers arising from its diffusion Well, what is to be done in this direction? Several ways are open One's first thought might be to consign all persons suffering from tuberculosis of the lungs whose sputum contains tubercle bacilli to suitable establishments This however, is not only absolutely impracticable but also unnecessary For a consumptive who coughs out tubercle bacilli is not necessarily a source of infection on that account so long as he takes care that his sputum is properly removed and rendered innocuous. This is certainly true of very many patients, especially in the first stages, and also of those who belong to the well to do classes and are able to procure the necessary nursing But how is it with people of very small means? Every medical man who has often entered the dwellings of the poor, and I can speak on this point from my own experience, knows how sad is the lot of consumptives and their families there The whole family have to live in one or two small ill ventilated rooms The patient is left without the nursing he needs because the able-bodied members of the family must go to their work. How can the necessary cleanliness be secured under such circumstances? How is such a helpless patient to remove his sputum so that it may do no harm? But let us go a step further and picture the condition of a poor consumptive patient's dwelling at night. The whole family sleep crowded together in one small room However cautious he may be the sufferer scatters the morbid matter secreted by his diseased lungs every time he coughs and his relatives close beside him must inhale this poison. Thus whole families are infected. They die out and awaken in the minds of those who do not know the infectiousness of tuberculosis the opinion that it is hereditary, whereas its transmission in the cases in question was due solely to the simplest processes of infection which do not strike people so much because the consequences do not appear at once but generally only after the lapse of years. Often under such circumstances the infection is not restricted to a single family but spreads in densely inhabited tenement houses to the neighbours, and then as the admirable investigations of Biggs have shown in the case of the densely peopled parts of New York, regular nests or foci of disease are formed. But if one investigates these matters more thoroughly one finds that it is not poverty *per se* that favours tuberculosis, but the bad domestic conditions under which the poor everywhere but especially in great cities, have to live For, as the German statistics show, tuberculosis is less frequent even among the poor, when the population is not densely packed together and may attain very great dimensions among a well to-do population when the domestic conditions especially as regards the bedrooms, are bad as is the case, for instance among the inhabitants of the North Sea coast. So it is the e poor that we have to regard as tuberculosis, it is out of them ps up anew, and it is to the that we must first and foremost direct our attention if we wish to attack the evil at its root and to wage war against it with effective weapons This being so it is very gratifying to see how efforts are being made in almost all countries to improve the domestic conditions of the poor. I am also convinced that these efforts, which must be promoted in every way, will lead to a considerable diminution of tuberculosis. But a long time must elapse ere essential changes can be effected in this direction, and much may be done meanwhile in order to reach the goal much more rapidly.

If we are not able at present to get rid of the danger which small and overcrowded dwellings involve, all we can do is to remove the patients from them and, in their own interests and that of the people about them, to lodge them better, and this can be done only in suitable hospitals. But the thought of attaining this end by compulsion of any kind is very far from me; what I want is that they may be enabled to obtain the nursing they need better than they can obtain it now. At present a consumptive in an advanced stage of the disease is regarded as incurable and as an unsuitable inmate for a hospital. The consequence is that he is reluctantly admitted and dismissed as soon as possible. The patient, too, when the treatment seems to him to produce no improvement and the expenses, owing to the long duration of his illness, weigh heavily upon him, is himself animated by the wish to leave the hospital soon. That would be altogether altered if we had special hospitals for consumptives, and if the patients were taken care of there for nothing, or at least at a very moderate rate. To such hospitals they would willingly go; they could be better treated and fed there than is now the case. I know very well that the execution of the project will have great difficulties to contend with, owing to the considerable outlay it entails. But very much would be gained if, at least in the existing hospitals, which have to admit a great number of consumptives at any rate, special wards were established for them in which pecuniary facilities would be offered them. If only a considerable fraction of the whole number of consumptives were suitably lodged in this way a diminution of infection, and consequently of the sum-total of tuberculosis, could not fail to be the result. Permit me to remind you in this connexion of what I said about leprosy. In the combating of that disease also great progress has already been made by lodging only a fair number of the patients in hospitals. The only country that possesses a considerable number of special hospitals for tuberculous patients is England, and there can be no doubt that the diminution of tuberculosis in England, which is much greater than in any other country, is greatly due to this circumstance. I should point to the founding of special hospitals for consumptives and the better utilisation of the already existing hospitals for the lodging of consumptives as the most important measure in the combating of tuberculosis, and its execution opens a wide field of activity to the State, to municipalities, and to private benevolence. There are many people who possess great wealth and would willingly give of their superfluity for the benefit of their poor and heavily afflicted fellow-creatures, but do not know how to do this in a judicious manner. Here is an opportunity for them to render a real and lasting service by founding consumption hospitals or purchasing the right to have a certain number of consumptive patients maintained in special wards of other hospitals free of expense.

As, however, unfortunately, the aid of the State, the municipalities, and rich benefactors will probably not be forthcoming for a long time yet, we must for the present resort to other measures that may pave the way for the main measure just referred to and serve as a supplement and temporary substitute for it. Among such measures I regard obligatory notification as specially valuable. In the combating of all infectious diseases it has proved indispensable as a means of obtaining certain knowledge as to their state, especially their dissemination, their increase, and their decrease. In the conflict with tuberculosis also we cannot dispense with obligatory notification; we need it not only in order to inform ourselves as to the dissemination of this disease, but mainly in order to learn where help and instruction can be given, and especially where the disinfection which is so urgently necessary when consumptives die or change their residences has to be effected. Fortunately it is not at all necessary to notify all cases of tuberculosis, nor even all cases of consumption, but only those that, owing to the domestic conditions, are sources of danger to the people about them. Such limited notification has already been introduced in various places—in Norway, for instance, by a special law, in Saxony by a Ministerial decree, in New York, and in several American towns which have followed its example. In New York, where notification was optional at first and was afterwards made obligatory, it has proved eminently useful. It has thus been proved that the evils which it used to be feared the introduction of notification for tuberculosis would bring about need not occur and it is devoutly to be wished that the examples I have named may very soon excite emulation everywhere.

There is another measure connected with notification—viz., disinfection, which, as already mentioned, must be effected when consumptives die or change their residence in order that those who next occupy the infected dwelling may be protected against infection. Moreover, not only the dwellings but also the infected beds and clothes of consumptives ought to be disinfected. A further measure, already recognised on all hands as effective, is the instructing of all classes of the people as to the infectiousness of tuberculosis and the best way of protecting oneself. The fact that tuberculosis has considerably diminished in almost all civilised states of late is attributable solely to the circumstance that knowledge of the contagious character of tuberculosis has been more and more widely disseminated and that caution in intercourse with consumptives has increased more and more in consequence. If better knowledge of the nature of tuberculosis has alone sufficed to prevent a large number of cases this must serve us as a significant admonition to make the greatest possible use of this means and to do more and more to bring it about that everybody may know the dangers that threaten them in intercourse with consumptives. It is only to be desired that the instructions may be made shorter and more precise than they generally are, and that special emphasis may be laid on the avoidance of the worst danger of infection, which is the use of bedrooms and small ill-ventilated workrooms simultaneously with consumptives. Of course the instructions must include directions as to what consumptives have to do when they cough and how they are to treat their sputum. Another measure, which has come into the foreground of late, and which at this moment plays to a certain extent a paramount part in all efforts for the combating of tuberculosis, works in quite another direction. I mean the founding of sanatoria for consumptives.

That tuberculosis is curable in its early stages must be regarded as an undisputed fact. The idea of curing as many tuberculous patients as possible in order to reduce the number of those that reach the infectious stage of consumption and thus to reduce the number of fresh cases w therefore a very natural one. The only question is wheth the number of persons cured in this way will be gr enough to exercise an appreciable influence on the ret gression of tuberculosis. I will try to answer this questi in the light of the figures at my disposal. Accordi to the business report of the German Central Ca mittee for the Establishment of Sanatoria for the Cu of Consumptives, about 5500 beds will be at the dispos of these institutions by the end of 1901, and then, if assume that the average stay of each patient will be thr months, it will be possible to treat at least 20,000 patien every year. From the reports hitherto issued as to the resu that have been acheived in the establishments we learn furth that about 20 per cent. of the patients who have tubercle baci in their sputum lose them by the treatment there. This is t only sure test of success, especially as regards prophylax If we make this the basis of our estimates, we find that 4,0 consumptives will leave these establishments annually cured. But, according to the statistics ascertained by t German Imperial Office of Health, there are 226,000 perso in Germany over fifteen years of age who are so far gone consumption that hospital treatment is necessary for the Compared with this great number of consumptives the succe of the establishments in question seems so small that material influence on the retrogression of tuberculosis general is not yet to be expected of them. But pray do n imagine that I wish by this calculation of mine to oppo the movement for the establishment of such sanatoria in a way. I only wish to warn against the over-estimating their importance which has recently been observable various quarters, based apparently on the opinion that t war against tuberculosis can be waged by means of sanator alone and that other measures are of subordinate value. reality the contrary is the case. What is to be achieved the general prophylaxis resulting from recognition of t danger of infection and the consequent greater caution intercourse with consumptives is shown by a calculation Cornet's regarding the decrease of mortality from tuberculos in Prussia in the years 1889 to 1897. Before 1889 t average was 31·4 per 10,000, whereas in the period named it sank to 21·8, which means that in that short space of time the number of deaths from tuberculosis was 184,000 less than was to be expected from the average of the preceding years. In New York, under the influence of the general sanitary measures directed in a simply exemplary manner by Biggs, the mortality from tuberculosis has diminished by more than 35 per cent. since 1886. And it must be remembered that both in Prussia and in New York the progress indicated by these figures is due to the first beginnings of these measures. Considerably greater success is to be expected of their further development. Biggs hopes to have got so far in five years that in the city of New York alone the annual number of deaths from tuberculosis will be 3000 less than formerly.

Now, I do indeed believe that it will be possible to render the sanatoria considerably more efficient. If strict care be taken that only patients be admitted for whom the treatment of those establishments is well adapted and if the duration of the treatment be prolonged it will certainly be possible to cure 50 per cent. and perhaps still more. But even then, and even if the number of the sanatoria be greatly increased, the total effect will always remain but moderate. The sanatoria will never render the other measures I have mentioned superfluous. If their number becomes great, however, and if they perform their functions properly, they may materially aid the strictly sanitary measures in the conflict with tuberculosis.

If now, in conclusion, we glance back once more to what has been done hitherto for the combating of tuberculosis, and forward to what has still to be done, we are at liberty to declare with a certain satisfaction that very promising [illegible] ade. Among these I reckon [illegible] ngland, the legal regulations [illegible] and Saxony, the organisa- [illegible] ork (the study and imitation [illegible] ecommend to all municipal [illegible] oria, and the instruction of the people. All that is necessary is to go on developing these beginnings, to test and, if possible, to increase their influence on the diminution of tuberculosis, and wherever anything useful has yet been done to do likewise. If we allow ourselves to be continually guided in this enterprise by the spirit of genuine preventive medical science, if we utilise the experience gained in conflict with other pestilences, and aim, with clear recognition of the purpose and resolute avoidance of wrong roads, at striking the evil at its root, then the battle against tuberculosis, which has been so energetically begun, cannot fail to have a victorious issue.

An Address

ON

THE PREVENTION OF TUBERCULOSIS IN THE DIFFERENT CIVILISED NATIONALITIES.

Delivered at the Third General Meeting of the British Congress on Tuberculosis on July 24th,

By PROFESSOR P. BROUARDEL,

DEAN OF THE FACULTY OF MEDICINE OF PARIS, MEMBER OF THE INSTITUTE

MR. PRESIDENT, LADIES, AND GENTLEMEN,—Mortality from tuberculosis varies according to the country. In some cases it is accountable for a sixth, a fifth, and sometimes a fourth of the total mortality. Havoc such as this makes it compulsory that all nations and governments should strictly inquire into and adopt measures to arrest the propagation of a disease which in these days is the greatest enemy of the human race. The wonder is that the voice of alarm has been so long in making itself heard and that for centuries our ancestors [illegible] assively on the disasters going on [illegible] several reasons for this apparent [illegible] gle was considered useless, the [illegible] not known how it spread. Exaggerating the import of some observations it was agreed that [illegible]s was hereditary. They were lulled to sleep by this formula which served as a pillow for idleness and exempted them from investigating the origin of the mischief. Popular observations were looked upon as old wives' tales—e.g., those of Morgagni, who in the seventeenth century stated that in Italy it was customary to burn the bedding of persons who had died from phthisis, and who declared that he was frightened to make a post-mortem examination on cases of phthisis.

But when, on Dec. 5th, 1865, Villemin showed experiments at the Academy of Medicine which proved the real presence of the contagion, when our illustrious colleague Professor Robert Koch had discovered and demonstrated to the medical world the agent of this contagion, everyone felt that a new way was opened to humanity and every nation wished to profit for the public good by the recent scientific discoveries. Before the men of science whom I have just mentioned had actually made known their discoveries, you English people had already begun the struggle. Convinced by observation that tuberculosis thrived in dark and damp dwellings, in 1836—nearly 70 years ago—you passed a law providing for the construction of healthy houses. And since that date your zeal has not abated. You have, with admirable perseverance, passed more than 10 Acts of Parliament, you have rendered salubrious the dwellings of the poor, the workshop, the town, and the whole kingdom. This effort has been described by the name of the Queen who presided over its direction—the Victorian Era. No greater homage could be paid to Her Gracious Majesty, and in the name of all my countrymen I unite with my English colleagues in adopting this characteristic name for the crusade that was undertaken and for the success obtained. You have diminished mortality in England from tuberculosis by 40 per cent. Yours is the honour. It will be ours to follow in your steps. I was asked by the committee to make the subject of my address the measures adopted by different nations for the prevention of consumption. This I agreed to do, but I must at the same time make a confession. I depended too much on my wish to please my excellent colleagues whose request seemed so feasible; but, unfortunately, precise information is difficult to collect, and the time at my disposal for its verification was very short, so that there will, I fear, be lacunæ, probably even errors. I shall be pleased in either case to have my attention drawn to them and I entreat my colleagues to do so; if they comply, thanks to them and to you the wish expressed by the committee will be carried out and every nation may, by hearing what its neighbours have done, gain instruction and be inspired by motives of emulation beneficial to all.

Gentlemen, the grounds for the prevention of tuberculosis are identical in every country. On this question the entire medical profession of the world is united. Tuberculosis is avoidable and curable. The methods used to bring this about are the same in all countries, but according to the impetus given to the movement by the men of science in the different nations and according to [illegible] have taken the fir[illegible] moment on legisla[illegible] into force that [illegible] turbs inveterate habits, and that has to be carried out in the bosom of the domestic hearth, when it is called for by public opinion—when all are convinced of its benefits and everyone recognises the danger of his vicious habits and is ready personally to reform them and to require his neighbour to do the same. This is the state of things in England. This system seems to me the only efficacious one and the first thing which is indispensable is to educate public opinion. How is this *anti-tuberculous education* of public opinion to be carried out? You founded in England in 1899, under the presidency of His Royal Highness the Prince of Wales, a National Association for the Prevention of Consumption and other Forms of Tuberculosis. Its object is to carry out prevention by educating the masses. You drew up short, practical pamphlets. As a model I may quote "The Crusade against Consumption" (48 pages, price 6*d.*), "Milk and Tuberculosis," "Fresh Air and Ventilation," "How to prevent Consumption," &c., and distributed them freely. At the head of this association I find names that I recognise with respect—those of the gentlemen who inaugurated this Congress. Germany founded societies for the construction of sanatoria and then societies for the propagation of the idea, to popularise sanitary ideas. These societies are small and scattered in different localities, forming provincial groups. They, too, publish popular pamphlets.

In Belgium there is a national league against tuberculosis, with its seat in Brussels. Each province has an independent branch. In Norway the Storthing voted 40,000 crowns for the purpose of printing and distributing a popular work on tuberculosis by Dr. Klaus Haussen, and 2000 crowns to form a travelling fund for doctors wishing to gain information about the management of sanatoria. In France the Society for the Prevention of Tuberculosis by Popular Education, under the direction of Dr. Peyrot, has collected together those who can teach with authority. I refer to such men as Lavisse, Matignon, Victorien Sardou, Landouzy, &c. Many of us have addressed meetings explaining rules of prophylaxis in the provinces, where, on every hand, anti-tuberculous movements are springing up. I made use of my position as president of the Polytechnic Association to institute popular education in Paris. This year 88 lectures on tuberculosis have been given to 12,000 pupils of this association. Thus gradually in all countries the public are beginning to realise that personal care and cleanliness are necessary to obviate contagion, and are also realising that other idea, to my mind equally important, that a consumptive patient is only dangerous if the necessary precautions are not taken around him, and if he himself does not take them to protect his relatives, friends, and fellow-workmen from contagion.

Tuberculophobia must not be produced, the patient must not be made a pariah. Long before our time a consumptive person has lived for many months without contaminating wife and children. The danger is in the sputum, which contains thousands of contagious germs. To expectorate on the ground is a disgusting and dangerous habit. Once this habit has quite disappeared tuberculosis will decrease rapidly. What rôle, as a matter of fact, does this sputum play in the subsequent propagation of the disease? It varies in different cases. Collected and shut up in a private, or common but *antiseptic, spittoon, destroyed by incineration or some other* measure, it is dangerous to no one. Thrown into dry and well-lighted surroundings, exposed to the rays of the sun, it will soon lose its dangerous properties. But if it remains in damp and dark surroundings, it will maintain its activity for a long time. Thus it is that tuberculosis claims more victims from gloomy, ill-ventilated, dark dwellings. All nations have recognised this, but England has the double merit of recognising the primary importance of this problem and of having solved it successfully in a manner peculiarly her own. Recognising that insalubrious dwellings are one of the most potent agents in the propagation of tuberculosis, the legislations of the different countries have kept this cause of insalubrity well in view, and have made laws ordering the destruction of unhealthy dwellings. You, since 1836, have directed your legislation towards the construction of healthy abodes and this action on the part of the Government has led to the intervention of benefactors whose memory should be kept green in the minds of those interested in public health.

In Germany private initiative has not been so successful. Belgium has been one of the most enthusiastic nations in taking up the movement in favour of healthy dwellings. In Denmark building societies have flourished best of all. In 1600 Christian IV. set the example by erecting houses with gardens for the employés of his house. But if tuberculous germs fall in an ill-lighted, damp house they maintain their activity for a long time, whether the house is in town or country. In these surroundings population is often very dense. It is no uncommon thing to see one room in Paris occupied by five, six, eight, and sometimes 12 persons. They are continually coming in contact with one another, chances of contagion are increased by this fact alone, and in addition to the limited space has to be added the dirtiness of the occupants, or, as I should say, the impossibility of keeping sufficiently clean. Thus small tuberculous foci are created which invade the whole house; the workmen and employés carry the germs of disease into their workshops and offices and soon make a large tuberculous focus of the town. But I do not wish to mislead. A town is not *in toto* unhealthy. In the same town, quarters adjoining one another may have a mortality from tuberculosis which varies inversely; mortality from tuberculosis in districts in Paris varies from 10 to 100 per 10,000 *inhabitants*. However, in every quarter there are hotbeds of tuberculosis. These are what we have to find and to demolish. Above all else, new dwellings equally unhealthy must not be constructed, for they are a danger to a city and country. In most of the towns in all countries building plans of new houses have to be submitted for approval to the *local sanitary authorities*. It is a necessary precaution which cannot be too strictly enforced.

The evils of an unhealthy dwelling are not confined to the risk of contagion just referred to. The want of air and light acts on the nutrition of the inmates, children pine away, the strongest men cannot withstand it, every human being living in these places is the destined prey (infectious diseases; and if we only consider phthisis the become predisposing causes of consumption, transformin the strongest man and putting him on a par with th condition of those born of tuberculous parents. In th latter heredity is not direct, one is not born tuberculous but predisposed to tuberculosis. The English, German Italian, French, and other laws that I referred to moment ago are therefore warranted, and should be enacte perseveringly, especially at a moment when there is tendency in all countries to concentrate in the towns th greater part of the populations. By looking after th salubrity of the towns the health of the whole land i protected. Unhealthy dwellings cause other disasters. Dar and crowded as they are cleanliness is difficult, if not im possible, to preserve; they are not pleasant to pass the time in, and the workman stays in his home as little as possible; he eats there and sleeps there, but the rest of his time is spent in the public-house. J. Simon was right in saying: "The wretched lodging is the purveyor of the public-house," and we can add to it that the public-house is the purveyor of tuberculosis. In fact, alcoholism is the most potent factor in propagating tuberculosis. The strongest man who once taken to drink is powerless against it. Time is short for me now to draw comparisons between the laws force in different countries—those which are proposed, priv efforts, associated efforts, and temperance societies. B can say that a universal cry of despair arises from the wh universe at the sight of the disasters caused by alcoholi Any measures, State or individual, tending to limit ravages of alcoholism will be our most precious auxiliarie the crusade against tuberculosis, but the question is too la a one to deal with here. Still, I should like to draw attent to a mistake made too easily in the different countries Ministers who have the charge of the financial departmen the State. They like to calculate the sum which the State g from the duty on alcohol, but they should deduct from it cost to the community of the family of the ruined drunka his degenerate, infirm, scrofulous and epileptic childr who must have shelter. *This invasion of alcoholism* ough be regarded by every one as a public danger, and t principle, the truth of which is incontestible, should inculcated into the masses—that the future of the world be in the hands of the temperate. The dangers surroundi a man in an unhealthy home are the same when for his wo his duties, his pleasure, through illness, or under constrai a man lives all or part of the day in a centre where ot people are assembled, where unhealthy conditions and ov crowding exist. If he is well, his companions dangerous to him; if he is ill, he is dangerous to the This peril *from common life* inseparable from advance civilisation is continually growing: it is the penalty a accounts for the threatening increase in tuberculo Brought face to face with those predisposed by their fami history, by the unhealthiness of their dwellings, it has be recognised as a duty in some countries to make an attem to restore these tottering frames and to render them capab of baffling with the dangers that threaten them. It w adjudged with reason that childhood and youth would the easiest period of life to influence. Thanks to t help of some towns and of private initiative in Ita and France and in other countries, sanatoria by t seaside have been established for weakly and scrofulo children. There are 14 in France which accommodat more than 2000 children a year, and with exceller results. May I be allowed to recall the fact that we ow this success chiefly to the unfailing activity and propagand undertaken by our revered master, Dr. Bergeron. Inspire by the same idea, some countries have started holida colonies and temporary visits to places by the sea or in th mountains. Everything done in this direction will help rescue *from contagion those who, thanks to the* generosity private individuals, can profit by these health-restoring visi In 1893, with the same object in view, Madame Hervie started at Sedan working gardens for children, young peop and their parents. These gardens occupy more than 20 square metres around the town, and accommodate 3 families composed of 1251 persons. The society supplies tools, seeds, and manure to each family. In 1894 the Jesuit Father Volpette started the working gardens at St. Etienne. They cover about 42 acres and accommodate 410 families, composed of 2460 persons. There are working gardens at Bercy and some are now being made at Fontainebleau and at Villeurbane, near Lyons.

Before touching on the question of the cure of tuberculosis I should like to say a few words about measures adopted to prevent tuberculous contagion by food. Since Chauveau showed that it was possible for tuberculous germs in food to produce tubercles in the intestinal tract attention has been turned to precautions for preventing the consumption of meats and milk from tuberculous animals. As far as meat is concerned, surveillance of the slaughter-houses in large towns achieves this. In Belgium this measure is also made to apply to the country, but I do not know of any other kingdom where private slaughter-houses are inspected, and in them it is that phthisical cows, measly pigs, and diseased animals of any kind are slaughtered, and are able to escape inspection. This injurious food is consumed either as fresh meat, or in the form of pâtés or sausages from which the tuberculous viscera have not been removed. Another danger is the hawking of meat in pieces. It is rife especially in the large towns. Butchers receive daily quarters of meat despatched by provincial butchers. This meat escapes inspection. With no wish to exaggerate the danger of the propagation of tuberculosis by meat it cannot be overlooked It is easy by means of legislation to protect the population from this method of contamination. Belgium has set us the example.

That the milk of cows with tuberculous inflammation of the udder is used is very clear. Your great hygienist, the late Sir Richard Thorne, while pointing out that in England the mortality in general of adults from phthisis had diminished since 1850 from 45 per 100, regretted to see that from the same date infantile mortality from tuberculosis increased by 27 per 100. According to him this increase is entirely due to tuberculosis in the abdomen caused by ingestion of contaminated milk in infants under a year old; for in England cowhouses are not inspected. In France, to all appearances, the law allows this surveillance. It is entrusted to mayors, but to put the law into execution the mayors must know the cows suffering from tuberculous mammitis, and they can only know this if the owner reports it. Now the dairies only report their cows when their milk is dry, when, in fact, they are no longer dangerous to the consumers. It is well to add that in large concerns the milk from different sources is mixed, and one cow only need be the victim of tuberculous mammitis in order to contaminate all the milk with which its milk is mixed. To prevent this method of propagation measures of strict inspection should be adopted, such as have been in use for several years in Denmark, Sweden, and Norway to the great advantage of public health. Until such necessary measures are actually adopted there remains the simple mode of avoiding risk from milk [illegible] be widely made known in spite [illegible] e which wrongly holds that boiled milk is less nutritious and indigestible.

If a man is the victim of tuberculosis everything possible should be done to cure him, for *he can be cured*. There is no doubt of this. From my personal experience at the Morgue in Paris, where I frequently make post-mortem examinations on accidental deaths, I can state that in half the cases, if the person on whom the examination is made has lived in Paris for about 10 years, I find healed tuberculous lesions, either in the form of cretaceous transformation or fibrous cicatrisation. I may add that it is quite certain that those on whom necropsies are held in almshouses, hospitals, and the Morgue, have certainly taken none of the precautions we consider necessary. In spite of often deplorably dirty habits the system has been strong enough to resist the ravages of the disease. These anatomical results have also another meaning. These lesions, in the majority of cases, are not phthisis in an early stage manifested by small disseminated foci; they are cicatrices of large foci, sometimes of wide, completely cicatrised cavities Phthisis, therefore, is curable, even in its most advanced stages. This is maintained not only by anatomo-pathologists, but by all medical men who have made a special study of the disease. Grancher sums the matter up thus: "Tuberculosis is the most easily cured of chronic diseases."

As a tuberculous patient can be cured everything possible must be done to bring this about by careful organisation. The medical man being himself firmly convinced that his patient can be cured will [illegible] his way [illegible] that he c[illegible] losis he [illegible] the natu[illegible] appearances until the time came when the case was hopeless. Now that tuberculosis can be cured he can behave in just the opposite way. If it is true that in every stage tuberculosis can be c[illegible] made to [illegible] stage wh[illegible] power of resistance in the patient's system. The patient and his family should be told that he has a serious disease, but that it is curable. This change of demeanour in the medical man will only be possible when he is able to tell the patient the best scientific methods of treatment for him to use.

What are the best methods? How are they carried out in the different countries? In this address I am dealing only with the disease as it affects working men and employés. I am leaving out of the question well-to-do patients, though these may gain some idea from it of the rules to be observed. The remedies to be recommended vary according to the stage to which the disease has got, and also if the patient is single, married, or the father of a family. Three distinct periods may be defined. In the earliest the patient coughs and has a cold. What does he generally do? Either he takes no notice of it or he asks the chemist for a mixture for his cough. Days, weeks, and months go by, and if the weather is inclement he gets worse; if it is mild he has periods of being better, followed by more serious attacks. Then fever and wasting set in and he has to give up his work. He thinks illness has just begun. We know that he is entering the second stage, when even skilled treatment is probably useless. The first stage of the disease, therefore, interests us most, when intervention is of use. In what way can we be of use to a patient in the first stage?

In Germany there are polyclinics for tuberculosis in the large towns, where a medical man provided with the things necessary attends to the patients who come to consult him, either throughout their illness or till the patient can be admitted into a sanatorium A committee, composed of benevolent men and women in large numbers, looks after the patient at home, tells his wife what to do, sees that his home is kept clean, and looks after necessary prophylactic measures. As far as possible the misery consequent on the bread-winner being out of work is relieved from a bank, kept up like the sanatoria banks, to assist such cases M. Calmette conceived the same idea, but he went farther and advised that, instead of waiting for the workman to come for advice, they should go and meet him by inviting him to come to a dispensary run on the same lines as the German polyclinics. This is his own description of his project that he gave in 1899:—"Instead of waiting till the patient with tuberculosis comes to consult a doctor and is driven to give up his work I think that it would be better to establish the principle of going to him and offering him help before he finds out even that he is dangerously ill. I should like to be able to hunt out tuberculosis as soon as ever it has begun and to be able then and there to give the sufferer advice and the care necessary, while generally keeping him in his own family circle." M. Calmette has carried out his proposal; he opened an anti-tuberculous dispensary at Lille called Emile Roux, and it has been eminently successful Dr. Bonnet has founded a similar institution in Paris, in the Montmartre quarter, and others are about to be established, one at Vaugirard, with municipal aid. Experience shows that workmen do not shun these dispensaries; some come because they have a cough, others because they know themselves to be attacked. As far as I can see the best way to ferret out disease would be to have one or more agent-workmen, foremen-workmen, if it were possible. They are the ones to notice when their comrades cough; they could advise them to go to the dispensary. Alive to the dangers of a badly kept workshop or yard they superintend its being kept clean and in order; they actually carry out anti-tuberculous education. Those who visit the dispensary receive the necessary attention from the medical men and are told the danger of dissemination by sputum, alcoholism, &c. They are looked after; they get meat gravy—one or two meals, as far as funds will allow. Their families are helped and their home is kept an eye on from the hygienic point of view; as far as possible the misery by which the poor man is threatened is kept away from him. Among these patients some are found who must be sent to a sanatorium. If the patient is an unmarried man, and if he can be sent to a sanatorium, his chances of recovery are very great, but for a married man to go means that his wife and family must be provided for during his absence and his mind relieved of all anxiety on their account.

It is not my business to deal with the question of building and management of a sanatorium. We need only remember that they should be private, aseptic, disciplined, and worked on Dettweiler's principle—physical and moral rest, stuffing, and open-air treatment. In Germany this system has been carried out most enthusiastically through the assistance of private benevolence and municipal, industrial, and parochial aid; the State has generously supported the effort, recognising its value. In Germany there are 83 public sanatoria open or ready to open. They accommodate 12,000 patients a year. They have been built by local insurance, by sickness banks, by the manufacturers who have combined to found sanatoria for their workpeople, and by parishes which have united for the purpose. There are most of the latter. In some parts a tax of from a penny a head has been exacted. The State has founded several sanatoria for its servants; the forests department, railway department, and the State of Hamburg. The Commission of the Budget of the Reichstag decided to build State sanatoria under the control of the Ministry of the Interior. The treatment lasts at least 90 days, and experience has shown that it was good for the patients to spend another month in the year following recovery at the sanatorium. Under these circumstances how long do the patients keep better? Of those who leave the sanatorium in what is considered a satisfactory condition it has been shown that 46 per cent. in 1896, 47 per cent. in 1897, 58 per cent. in 1898; 60 per cent. in 1899 were able to work. The cost per head per patient for the three months' stay amounts to eight francs per diem, including the cost of assistance given to the patient's family, which is a third of the amount. Germany's example has been followed. England, Scotland, Australia, and Canada have erected some few sanatoria. In Austria Schrötter had the Sanatorium d'Alland built, with 300 beds. Chevalier von Kusy turned into small sanatoria some huts of the Ducke type. In the United States they set apart portions of hospitals to make consumptive wards of them. They made about 30 such small sanatoria. The Association of Alabama built one for prisoners, the Naval Department one for sailors. New York has actually six sanatoria. By the munificence of the Czar the Établissement Halila, in Russia, was built in 1897; and, since 1898, that of Tactzi, with two pavilions accommodating 20 beds for men and 20 beds for women. At Salta Princess Bariatinski has founded an establishment for schoolboys. The King of Sweden gave the sum collected at his jubilee (2,300,000 crowns) to build three sanatoria, Parliament voted 800,000 crowns for the same object, and the State gave the ground required for these three sanatoria. Denmark has already two sanatoria, and there is a scheme before Parliament for the erection of public sanatoria. Italy and the Netherlands and Norway have followed suit. In France several sanatoria have been opened: Hauteville, near Lyons; Agincourt, for Paris. Since 1876 we built the Home of Villepinte, and then that of Ormesson, for young tuberculous patients; and we may mention, in addition, the agricultural colonies of Cannet, the Jean Dollfus Home at Cannes, the Sanatorium of Gironde, that of Cimiez (near Nice), Argelez, and finally those which have recently been opened or will be—Lille, Nancy, Orléans, Versailles, Amiens, Le Havre, Marseilles, and (in Paris) the Bligny and Rouen sanatoria, &c. All nations have obeyed the same generous impulses, and the time will come when, instead of the poor tuberculous patient being given up to his sad lot, he will find if he is only in the first stage of the disease that by means of dispensaries and sanatoria there is always hope and often realisation of his recovery.

If the patient is beyond the first two stages when he asks for admission to the hospital, it must not be overlooked that he may still be cured, provided he can be made to see things as they are. He must be isolated in order that he may not be discouraged by the spectacle of his comrades' sufferings. Rules of isolation have been drawn up by Grancher and Thoinot for the patient and for his nurses; you have them in use in your own consumption hospitals. At Brompton in 20 years 15,000 consumptives have been cared for. No medical man or officer or nurse has been infected. This statement is supported by Dr. Williams, physician of the hospital, by Möeller, and by Masbrenier.

Gentlemen, when I was asked by the committee to tell you in my address, which I am sorry I could not make shorter, what steps had been taken by the different nations to carry out the crusade against consumption, I was also asked to consider the question from the international point of view. I do not think that it is possible to deal with consumption in this respect as plague, cholera, and yellow fever have been dealt with in order to prevent their being brought into a country. I do not know how any practitioner can state positively that a traveller at the frontier or the port is not consumptive. But it would be possible to take international steps in another way. Railway carriages might be disinfected as well as steamboats and hotels, and the traveller no longer exposed to germs of contagion. That would be of truly international import. The Minister or Public Works in France has recently sent a circular to railway companies calling their attention to the precautions necessary to obviate or to diminish risk from tuberculous contagion. In several countries, particularly in the United States, hotel-keepers who receive a consumptive client have to notify it to the municipal authorities, and compulsory disinfection of the room has to be gone through. The Minister of the Interior in Germany has brought in even more stringent measures. Every practitioner who attends a case of pulmonary or laryngeal tuberculosis is bound to report it in writing to the police as soon as he has made his diagnosis. After death from tuberculosis the room in which the patient has died has to be disinfected as have his belongings. Hotel proprietors, "furnished house" keepers, asylums, and other public institutions are compelled to notify at once every case of tuberculous disease which arises in their establishments. Notification, disinfection, salubrity of hotels, carriages, and steamboats are questions of an international character which might be advantageously dealt with by representatives of the different nations. The lesson to be drawn from the efforts that have been made by all nations to carry out a crusade against tuberculosis is that in conversation, in the public prints, and especially in prepared pamphlets, we should make it universally known that tuberculous contamination can be avoided, and that in addition the disease can be cured. Once convince our fellow citizens on these two points, and private initiative will be left behind; anti-tuberculous efforts, numerous now, will multiply and coördinate; parishes, provinces, and the State will not be able to stand aloof from a common effort, and we may reasonably prophesy that, united in one brave attempt, the whole civilised world will succeed in exterminating the cruellest scourge that has ever fallen on us, our children, and our friends, and which threatens the future of our countries.

Gentlemen, 10 years ago at the Congress of Hygiene in London, I spoke as follows:—"When at the beginning of a century one can inscribe the name of Jenner, and at its end that of Pasteur, the human race may rejoice; more has been done for it against misery, disease, and death than in any one of the centuries which have preceded it." All honour to the nineteenth century, but the century just begun, in its first year, sees the greatest effort that has ever been made in favour of public medicine. May no obstacle stand in our way, and may those who succeed us at the end of the twentieth century be able to bear witness that our conviction has not been fruitless and the results have answered the expectations of the nations that you, gentlemen of the Organising Committee, have brought together, with the highest and noblest motive that has ever animated the human race.

ROYAL ALBERT HOSPITAL, DEVONPORT.—The cost of carrying out the improvements in the Royal Albert Hospital, Devonport, has been heavier than was anticipated. Sir John Jackson has therefore given a donation of £500 to the building fund and the committee hope that further contributions will be received.

THE FALMOUTH DRAINAGE.—At the meeting of the Falmouth Corporation held on July 11th the General Purposes Committee recommended that a scheme of drainage, estimated to cost about £17,200, should be submitted to the Local Government Board for their approval, and application should be made to carry out the work. After a considerable discussion the mayor gave his casting vote in favour of the recommendation to adopt the scheme.

THE ADMINISTRATION OF THE MANCHESTER MILK CLAUSES, 1899.[1]

BY JAMES NIVEN, M.A., M.B., B.C. CANTAB.,
MEDICAL OFFICER OF HEALTH OF MANCHESTER.

THE evidence showing that tuberculous milk has been the cause of tuberculous disease demonstrated in the bodies of children who have died from tuberculosis or from other diseases is, from a variety of causes, rather scanty. Some evidence has, it is true, been collected to show that there is a disproportionately large amount of primary abdominal tuberculosis in young cattle, but no demonstration has been given that this is due to milk. Exact post-mortem examination records show that there is an almost complete absence of tuberculous lesions in new-born infants, while the proportion of children suffering from tuberculous lesions, abdominal and other, steadily increases with advancing months and years. Such records also show that primary abdominal tuberculosis is much more frequent in infants than in adults. It is open to infer that the food of young children and of young cattle is more liable to produce tuberculosis than the food of adults and of full-grown cattle. This is, however, only a probable conclusion. The conclusion is rendered much stronger by the evidence of feeding experiments, such as those made by Chauveau and Jöhne and repeated with milk from tuberculous udders for the Royal Commission on Tuberculosis (1895) by Dr. Sims Woodhead and Dr. Sidney Martin, which showed that the milk from tuberculous udders was virulently infective when fed to calves, kittens, pigs, and guinea-pigs. The Royal Commission were so much impressed by the evidence which they obtained on this subject that they recommended, *inter alia*, that for the purpose of excluding from their districts the milk of cows affected with tuberculosis of the udder or exhibiting clinical symptoms of the disease, local authorities should be given powers somewhat similar to those of sections 24–27 of the Glasgow Police (Amendment) Act, with power to slaughter such cows subject to compensation under the conditions named in the report.

In 1896, 1897, and 1898 a series of examinations of the cows within the city of Manchester and of suspected farms outside the city were made under the direction of the medical officer of health by the veterinary surgeon of the corporation, Mr. King, at first with a view to furnish evidence for the Royal Commission and subsequently to determine the lines which administrative action should take. In this preliminary work we are under a great obligation to Mr. Holburn, the present chief veterinary surgeon of the Markets Department, as well as for subsequent assistance. Professor Delépine undertook a careful investigation of the milks obtained from suspected udders and of the conditions to be observed in concluding that a particular milk was infectious. Professor Delépine had previously improved the inoculation test by showing that much increased accuracy and precision were obtained by inoculating guinea-pigs in the posterior limbs and obtained also other valuable results from his experimental investigations. Out of 10 samples of milk taken from indurated udders he found by microscopic examination and the inoculation test that only five were tuberculous From this and other observations it was concluded that veterinary observations alone do not suffice to determine whether an udder is tuberculous, and our subsequent experience amply confirms this conclusion. In 1897 and 1898 20 samples taken at railway stations were found to be tuberculous by Professor Delépine, 16 of the corresponding farms were visited by Mr. King, and on 14 out of 16 he found cows having indurated udders. It was not then considered necessary to conclude the evidence by examining the milk from these udders, though this ought to have been done. Ample evidence, however, had been secured to show that valuable results could be secured by taking advantage of the recommendation of the Commission already quoted.

The Sanitary Committee of the city determined, in September, 1898, to apply for similar powers to those enjoyed by Glasgow. As originally drafted, the Manchester milk clauses sought unlimited power of inspection of the cows on all farms supplying milk to Manchester, and provided for the exclusion, temporary or permanent, of milk from all cows with udders affected with any disease, as well as of the milk from all cows affected with advanced tuberculosis. Other corporations followed the example, but the opposition at first was concentrated on Manchester, and the clauses were materially curtailed before they reached Parliament. It was found impossible from the beginning to insert a clause providing for the slaughter of cows suffering from tuberculosis of the udder, or from advanced tuberculosis, though the necessity for this clause was clearly recognised. It was further found necessary at a town's meeting to remove advanced tuberculosis as a condition rendering the milk of a cow unfit for human food. Hence the powers asked for by Manchester were not so large as those asked by some other corporations. The corporations applying for powers were advised by the Local Government Board that they would be much more likely to get powers from Parliament if they could agree on a common set of clauses, and Mr. Fitzgerald was requested to prepare a draft of clauses, which he did, with the aid of the Local Government Board. The opportunity was thus presented of inserting a clause relating to the slaughter of cows, but the absence of previous authorisation was fatal to the proposal. The common clauses were considered by the Local Government Board, the Board of Agriculture, and the Associated Chambers of Agriculture, and in their final form presented both additions to, and diminutions of, the powers asked for by the various corporations. The clauses enacted in effect:—1. That a cow known to be suffering from tuberculosis of the udder must be isolated, and by isolation was meant isolation on the same farm. 2. Powers were given to inspect the cows, and to take samples of milk from particular teats, also to take samples of mixed milk produced, or sold, or intended for sale within the city. These powers, however, can only be exercised outside the city on the production of an order of a justice having jurisdiction in the place in which the farm is situated. 3. If the medical officer of health is of opinion that tuberculosis is caused, or is likely to be caused, to persons residing in his district from consumption of the milk supplied from any dairy, the dairyman may be summoned to appear before the corporation to show cause why an order should not be made prohibiting him from supplying milk within the city. 4. A dairyman supplying milk within the city who has in his dairy any cow affected with, or suspected of, or exhibiting signs of, tuberculosis of the udder, shall forthwith give written notice of the fact to the medical officer of health of the district which he supplies, stating his name and address and the situation of the premises where the cow is. Unfortunately, the penalty attaching to an offence under this section must not exceed 40*s*.

The manner in which the administration was planned out before these clauses were obtained, and in which it has still been found most convenient to administer them, is as follows. Inside the city the cows are systematically examined and if any suspicious condition of the udder is discovered by its veterinary surgeon a sample of milk is drawn into a sterilised bottle sterilised in Professor Delépine's laboratory (full particulars being recorded), and is sent forthwith to him on its return to the office of the veterinary surgeon. If the milk is found to be tuberculous the cowkeeper is requested to have the cow slaughtered under veterinary inspection and does so.

It will be seen that this usually entails waiting a month till the result of the inoculation test is obtained. But in all cases with suspicious characters the cowkeeper is informed of the views of the veterinary surgeon. In the case of farms outside the city samples of mixed milk are taken from cans as they arrive at the railway stations or from milk-carts and are submitted to Professor Delépine for examination. Should he declare a sample to be tuberculous an order is obtained from a justice having jurisdiction in the place where the farm is situate empowering the medical officer of health or his deputy, accompanied by the veterinary surgeon of the corporation, to visit the farm, inspect the cows, and take samples of milk from suspected udders. These samples are then sent to Professor Delépine for examination and it is upon this examination that the diagnosis of tuberculosis of the udder is decided. The farmer is then required to isolate the affected cow, but is advised by the medical officer of health in writing to have her forthwith slaughtered in the presence of the veterinary surgeon of the corporation. How far this has been successful, how far unsuccessful, will be seen by the details shown in the statement of the veterinary surgeon.[2] In all cases the cow has been disposed of, but the manner in which this has been effected clearly indicates the necessity for a clause requiring that the affected cow shall be slaughtered under supervision.

---

[1] A paper communicated to the British Congress on Tuberculosis. Section I., State and Municipal.

It will be noted that the detection of the tuberculous milk in the first instance, and the final diagnosis of the tuberculous udder, rest with the bacteriologist, and it might be supposed that the part of the veterinary surgeon is a somewhat subordinate one. This is by no means the case. The whole of the administration of these clauses, as carried out in Manchester, rests upon the assumption that, given a mixed milk proved to be tuberculous, there must be amongst the cows producing it one or more affected with tuberculosis of the udder. Exception might be taken to this assumption on these grounds: (1) that the milk may be contaminated by a consumptive person or otherwise in transit; (2) that it might be contaminated by tuberculous dust or dirt in the cowshed; and (3) that the milk might be infected by the presence in the cow of a generalised tuberculosis without the udder being affected. It is also conceivable as the result of fouling of the udder with infected excreta, without lesion of the udder.

With regard to (1) it is an almost inconceivable occurrence with a covered can, and all cans are covered and should be locked; (2) is a possibility in a highly infected cowshed, especially after it has been recently swept or if the affected cow is suffering from tuberculous disease of the intestines, but under ordinary conditions could hardly yield a sufficient number of bacilli to infect the milk to the extent determined by Professor Delépine; (3) may occur as a pathological rarity, but even then infection of the udder would have started. On the other hand, it does not follow that an udder which has been invaded by tuberculosis to an extent sufficient to yield an infected mixed milk shall present any lesions to clinical examination. Of this we were well aware before the milk clauses came into operation. In one such instance where I persuaded the cowkeeper to have his cows tested with tuberculin the udder of one cow gave a very marked local reaction, showing the presence of disease, though no morbid condition was found on clinical examination On this fact, and on the well-known effect of tuberculin on local lesions, especially those of tuberculosis, was based our proposed use of the tuberculin test to determine, in advanced cases of tuberculosis, the condition of udders yielding no local signs. A reaction being obtained, it still remains necessary to examine the milk from the tuberculous udder to see whether it is tuberculous. The objection, then, urged against inferring from a tuberculous mixed milk the fact of one or more tuberculous udders being concerned in its production is scientifically of little value, and from the point of view of administration of none at all.

The fact that a mixed milk is tuberculous only serves to guide us in going to a particular farm, and if any flaw existed in our assumption this would mean only that the veterinary surgeon would not in all cases find tuberculous udders corresponding to the tuberculous mixed milk. Moreover, it has been quite clear, both to our veterinary surgeon and myself, that the power of detecting suspicious conditions in the udder is one which admits of considerable extension by practice, even in skilled hands, and it is in this difficult task that the important rôle of the veterinary surgeon lies. I am quite satisfied, from the udders which have been brought by Mr. Lloyd from slaughtered cows, that definite lesions are often so diffuse as to be most difficult of detection. Hence, when he states that he has seen three instances in which lesions, previously undetectable in udders yielding tuberculous milk, made their appearance during the continuance of his observations, I am prepared to accept the conclusion that the udder may be in a pathological condition, not to be discovered merely by manipulation, but quite adequate to produce in the milk large numbers of bacilli. As a result of following up 47 tuberculous milks he has found udders which were proved by subsequent examination of the milk to be tuberculous in 31 instances. In 15 instances a tuberculous udder has not been found. In one instance the result is not yet determined. In some cases the affected cows would appear to have been removed between the taking of the mixed sample and the subsequent visit of the veterinary surgeon to the farm. This might well happen, and by no means accidentally, but as a result of the milk being under examination. It is therefore highly satisfactory to find that in so high a proportion of cases the tuberculous udders have been traced. Such a result sufficiently proves our position that, given the mixed milk to be tuberculous, it is safe for all practical purposes to infer a tuberculous udder producing it. At the same time such a source of error and of misconduct need not exist. It would suffice to check it if all restriction on the inspection of outside farms were removed and if an additional veterinary surgeon were appointed to carry on such direct inspection. In case no tuberculous udder is found it suffices to subject the mixed milk to two or three further tests to determine whether this is due to an obscure udder condition or to some other cause If it is due to obscurity of the diseased state of the udder the mixed milk will continue to be tuberculous. In some cases the condition of the atmosphere of the cowshed and the udders of the cows should be tested in regard of their power to infect the milk under existing and under possible conditions. This I propose to have done.

The "order" section of the milk clauses has not been used in Manchester, except in one instance where a cowshed was grossly overcrowded and incurably dirty. Yet this section gives very extensive powers, and possibly it is owing to the fact that it may be used that no one has attempted to use milk from a condemned cow. It is quite a conceivable policy to rely on the order section alone, and not to send a veterinary surgeon to the farm, throwing on the farmer the onus of determining how his milk has become infected and of showing that he had taken effectual steps to stop the production of tuberculous milk. Were such a policy adopted the farmer would be obliged to call in a veterinary surgeon at his own expense who would give him a certificate that he had taken the steps required by the clauses The corporation would then satisfy themselves that the mixed milk from such dairy no longer contained tubercle bacilli and would doubtless refrain from making the order. The disadvantage of such a course would be that the sanitary authority would know nothing of the conditions under which milk was being produced, and it would also be a great hardship on the farmer to take this course. In the case of a dairy receiving and mixing milks from a number of farms this is the only course which could be adopted. It is quite evident that the order section would be most valuable in the case of persistent infection in a mixed milk when from one or another cause the source of the infection could not be ascertained. But we have had no such cases.

The clause requiring notification of suspicious conditions of the udder by farmers has been practically inoperative, directly. These conditions are not notified and the penalty is inadequate. But indirectly it has been of some service. When an udder has been shown to be tuberculous and a ready compliance is made with the request of the medical officer of health for the slaughter of the diseased cow in the presence of the veterinary surgeon no further action has been taken. But if the cow is removed, so that it cannot be satisfactorily traced, and if the udder has been such that notification ought to have been given, a prosecution ensues. In this roundabout manner some control is exercised over the disposal of the cows. But the penalty is inadequate, and a cow affected with tuberculosis of the udder should be forthwith slaughtered, under proper inspection, with a heavy penalty attached in case of evasion. I have indicated how these clauses have been carried out and how they might have been more severely administered, and the question presents itself whether their administration has been attended with a marked diminution in tuberculosis of the udder. If one might judge from the ferment which these clauses have excited one would expect that a considerable and steady diminution would have occurred The diminution has been considerable, but it has by no means been constant Of the mixed milks from 401 farms taken under the milk clauses 47 have proved tuberculous, or 11·7 per cent. Of 108 samples taken at railway stations before the milk clauses came into operation 20, or 18·5 per cent., were tuberculous. There has thus been an improvement in the milk samples taken at railway stations to the extent of 7 per cent., but the proportion of tuberculous udders has fluctuated. It may be that farmers supplying Manchester with milk will in future take additional precautions, and that a further improvement is only delayed. It was never anticipated that by these clauses tubercle bacilli would be altogether excluded from the milk-supply. The foundation of tuberculous udders remains behind in the tuberculous cows and in the dark, badly ventilated, and crowded cowsheds.

---

[2] Dr Niven's paper was followed by a statement from Mr. J. S. Lloyd, M.R.C.V.S., late Veterinary Surgeon to the Sanitary Committee of the City of Manchester, which we shall publish later.

What was hoped, however, was that a substantial proportion of infection would be intercepted and that the irritation generated by the discovery of tuberculous infection would turn the attention of farmers to the necessity of protecting themselves, either by systematic veterinary inspection and greater cleanliness, or by getting the tuberculin test used towards the total eradication of tuberculosis.

It may be that we are in too much haste to gather our fruit, but I must admit that I begin to doubt whether the operation of the milk clauses is adequate to the entire result expected. On the other hand, one cannot but feel some degree of sympathy with farmers in hesitating to go in for entire eradication of tuberculosis, until at all events the necessary conditions are clearly understood by them. It is not sufficient to extirpate tuberculosis from a herd; as determined by the most careful application of the tuberculin test; as much care is requisite in the complete disinfection of the cowsheds, so that the herd should always be purified in summer in the first instance. It is also requisite that the cows should have adequate housing and that the cowsheds should be at all times kept thoroughly clean. It is difficult to provide a feeding passage and fulfil the latter condition with less than 700 cubic feet of space in a cowshed with one row of cows, unless the cows are stalled two and two, when 600 cubic feet may be just made to suffice, but double stalls are a bad arrangement.

Cows must be adequately fed. We have evidence that inadequate feeding greatly aids the spread of tuberculosis. Inadequate feeding is otherwise unprofitable and is often due to want of knowledge. It is well worth considering whether a herd newly purified from tuberculosis should not be turned into a grazing field not recently used. Wonderful as are the results of the tuberculin test it is not infallible even when applied legitimately; and supposing one or two tuberculous cows are introduced into a herd housed in dark, crowded, badly-ventilated, and dirty cowsheds, the disease will spread or else the whole of our conceptions regarding the propagation of tuberculosis are erroneous. If, however, the cows and cowsheds are kept rigidly clean an odd tuberculous cow should not matter much. But this condition cannot be fulfilled with many of our existing cowsheds, and if it could it is difficult to convey to a farm-labourer a sense of its supreme importance. Nevertheless, until we are ready to adopt the measures requisite for the complete eradication of tuberculosis from dairy cattle I agree with Professor Delépine that we shall not cease to have a certain proportion of tuberculous milks. Meantime we are content to wait for a year or two until we see how far the milk clauses will assist us. I would, however, urge these points: (1) that cows shown to suffer from tuberculosis of the udder should be required by law to be forthwith slaughtered in the presence of the veterinary surgeon employed under the milk clauses; (2) that all restrictions on the inspection of herds supplying the district with milk should be removed; and (3) that a heavy penalty should be attached to failure to notify suspicious conditions of the udder.

STERILISATION AND PASTEURISATION v. TUBERCLE-FREE HERDS, &c.[1]

BY E. W. HOPE, M.D. EDIN.,

MEDICAL OFFICER OF HEALTH OF THE CITY AND PORT OF LIVERPOOL.

ONE of the dangers of the tuberculous infection of human beings arises from the consumption of raw milk taken from cows which are themselves suffering from tuberculosis—notably tuberculosis of the udder. The object of the discussion which I have been asked to open is to determine which of three methods suggested furnishes the most practicable and the best safeguard against this danger, always bearing in mind that if we decide to rely upon one and are in a position to apply it with certain effect we shall not necessarily exclude the others, unless we can be assured that in doing so we are not, whilst effecting security from one danger, discarding safeguards against others even more serious. It is obvious that numerous points are involved in the subject, some of which are difficult to dissociate from questions other than those which concern tuberculosis only. For example, measures taken with the sole object of checking an even more destructive form of disease—viz., diarrhœa—have proved *incidentally a safeguard against tuberculosis*; while, on the other hand, measures directed against tuberculosis have afforded a valuable protection from other forms of disease. We must look at the subject from the wide view of general sanitation, remembering for the moment that there are other evils to be conquered as well as tuberculosis, and also bearing in mind that communities, like individuals, in their efforts to free themselves from mischief may be doing harm to those of their neighbours who are less able to take care of themselves. In the remarks that I am about to make, and for the purposes of this paper, I shall take it for granted that the phrase, "properly cooled between the time of milking and the time of reaching the consumers," implies also cleanliness and all other sanitary requirements except those specifically directed against tuberculosis; and, furthermore, my observations will be restricted to those aspects of the subject which most concern the large centres of population.

The terms "sterilisation" and "pasteurisation," so far as the subject under consideration is concerned, have practically the same significance—viz., raising the temperature of the milk to a degree which is capable of destroying the tubercle bacillus; exposure to a temperature of from 170° to 180° F. for about from 20 minutes to half an hour is sufficient to destroy most pathogenic organisms. However, sterilisation and pasteurisation of milk possess one conspicuous advantage—viz., that the application of the safeguard is within the reach of every reasonably prudent and careful household, consequently for ease of application it is beyond any comparison with the other preventive measure to be considered. The objections to it do not appear to be important, but there are the facts to be reckoned with that in the lower quarters of every great town there are thousands of families neither prudent nor careful, and also that the population of this country as a rule prefer to take their milk raw. This preference results, no doubt, partly from thoughtlessness and partly from habit. Young children are trained to take it raw, and the belief is widespread that if the milk is raised in temperature to, say, 200° F., or even still nearer the boiling point, it is altered in flavour and constitution and is of less nutritive and digestive value than when it is given raw; the raw milk, in fact, is regarded as more nearly approaching the natural milk of the mother.

There is no clinical evidence whatever to show that sterilised or even boiled milk is less nutritious and valuable than raw milk. On the other hand, raw cows' milk, in addition tc [illegible] brings many others. The process of [illegible] dirty milker, from dirty udde[illegible]m this it may be passed through a dirty strainer into a dirty railway-can. It is discharged from the railway-can into smaller vessels in which it is hawked about the dusty streets, passing through some half-dozen other pots and pans before it reaches the nursery or the table of the consumer, involving a host of possible sources of contamination, not excepting the contamination of tubercle bacillus; in fact, it may be safely said there is no article of food in common use so constantly exposed to contamination or so suceptible of contamination as raw milk. The milk, on the other hand, as nature intended it to be given, is never once exposed to air, passing directly and at the time of its manufacture in the gland to the stomach of the young animal, and, apart from the possibility of disease in the gland, is bacteriologically clean and pure.

Sterilisation, valuable as it is as a final safeguard against tuberculosis, is, after all, only an expedient, and must not be put into so much prominence that the importance of the other safeguard is lost sight of, although we cannot take it for granted in considering the merits of different methods that essential accessories common to them all will be observed. The one merit of sterilisation is that it is an expedient easy of application and presenting few administrative difficulties. Beyond any question the ultimate advantage lies in obtaining the milk from herds free from tuberculosis. It is, in fact, comparable with the advantage of obtaining drinking water from a pure source instead of taking it from a contaminated one and relying upon purification afterwards. The first aim must be to ensure that the source of the milk is pure—in oth[illegible] are free from tuberculosis; or if thi[illegible] the law and public opinion, is[illegible] at least be free from any tuberculous disease of the udder or any tumour or condition of the udder simulating tuberculous disease, or, having regard to difficulties in diagnosis, we may with advantage go even a step further and demand that the udder in all cows from which milk is taken for human food shall be in a perfectly normal condition.

---

[1] A paper communicated to the British Congress on Tuberculosis. Section I., State and Municipal.

The main causes of tuberculosis in cows are notorious: close confinement in ill-ventilated, badly-lighted, ill-constructed and dirty cowsheds—defects all as easy to remedy as is removal from the cowshed of the obviously tuberculous animal before it can cause infection of the rest. In the city of Liverpool about 26,000 gallons of milk are consumed every day; one-half of it comes from cows (about 6000 in number) kept within the city, the other half comes from cows kept in the country and is sent in by rail. Within recent years that part of the milk-supply which comes from cows kept within the city has been practically free from tuberculosis. This has been brought about by the sanitation of the cowsheds, adequacy of air, light, and cleanliness, by systematic and frequent inspection of the cows by qualified inspectors with veterinary help, and by frequent bacteriological analysis of the samples of milk; these are the measures which have effected this end. I do not say that out of the 6000 cows in the city there is not a single one affected with tubercle, but merely that there are few with such form of tuberculous disease as would be likely to contaminate the milk-supply.

These methods and this system of inspection were not initiated without difficulty and opposition. There is no opposition now; every person acquiesces in advantages which have been gained. But there is another aspect to the question. Only one-half of the quantity of milk consumed in Liverpool is supplied from the city, the remaining half comes from the country districts. But surely, it may be said, if the cows kept in the cowsheds within a great and populous city are healthy, those coming from the sunny meadows of the country, with their fertile pastures and ample land, are free also. Unfortunately, experience does not bear this out; the milk sent in from the country is more frequently tuberculous. Thus, out of 422 town samples examined during 1899 and 1900 five were tuberculous, being less than 1 per cent.; but out of 490 country samples taken during the same period 20 were tuberculous, being a trifle over 4 per cent. How can we protect ourselves against this? A special Act of Parliament applying to a few great towns, including Liverpool, gives special powers to exclude from the city, under a penalty, the milk coming from the country cowsheds in which tuberculous cows are kept under dirty and insanitary conditions. But if it is difficult to deal with and to supervise the supply within our own city, it is evidently both costly and difficult to maintain a staff to send under the special Act of Parliament to the insanitary and tuberclo-ridden cowsheds of the country cowman, but having overcome these difficulties the broad national question comes in, for although we succeed in protecting ourselves what happens with regard to the diseased cows and the diseased milk? The dealer refrains from sending diseased milk to the protected city, but what is there to prevent him from sending his milk for sale and consumption to a district where no special Act of Parliament exists to enable the community to protect itself or from selling his diseased cows to a dairyman in another locality? This is not the way to secure a supply of milk from herds free from tuberculosis, but there can be little doubt that the action of the great cities will not only protect themselves but will to a certain extent protect the country districts also and will strengthen the hands of rural sanitary authorities. No doubt the great cities are financially better able to protect themselves; they have their larger and more costly staff, they have their bacteriological laboratories, their veterinary and medical officers, but at best they are but valuable allies to the rural sanitary authorities, and these, after all, must take their own action, since the protection the cities afford them is an indirect vicarious one and, as in cases which I have alluded to, there is nothing to prevent the cow- [illegible] diseased produce to rural districts after [illegible] from sending it to the great cities. Furthermore, the undoubted decline in the proportion of tuberculous milk sent in from the country may really mean that a larger proportion is consumed elsewhere. The subject is quite important enough for a Government department—e.g., the Local Government Board—to take in hand and appoint a special staff to supervise the milk-supply and all appertaining to it throughout the country.

I have no hesitation whatever in saying that it is quite possible to ensure that the milk-supply shall come from cows free from tuberculosis. Difficulties from ignorance, obstruction, and active opposition may be taken for granted, but these must be overcome, and the cowkeeper will learn in time that his own interests are identical with those of his customers, and by keeping healthy cows in a sanitary condition he will be a gainer in every way. It is only right to say that during last year samples of milk taken at the railway stations on arrival from the country do not appear to be more frequently tuberculous than the samples taken from the town. This may indicate one of two things: either a general improvement in the country cowsheds under the stimulus of city action, or, as in more cases than one which have come under my notice, dairymen who have been detected in sending in tuberculous milk have refrained altogether from sending milk to Liverpool and now send their milk elsewhere. These are points not to be lost sight of.

NATURAL IMMUNITY FROM TUBERC LOSIS IN NATAL, SOUTH AFRICA.[1]

BY JAMES F. ALLEN, M.D. R.U.I.,
DELEGATE FROM PIETERMARITZBURG, NATAL, SOUTH AFRICA.

SITUATION, TOPOGRAPHY, AND CLIMATE OF NATAL.

IN considering the means whereby the disease known "tuberculosis" may be repressed climatology must alwa take an important place, it being a matter of comm notoriety that in certain parts of the world, under certa conditions of climate, topography, and social relations, th disease is a scourge which almost threatens the existen of the human race; and again in other regions, and und different circumstances, it seems to have lost its power injuriously affecting man, though in some degree it may b known to exist locally. How the human race can exist i any country where this disease is known also to be, and b practically free from its affects, is a question so interesting important, and instructive that every effort should b made to explain such immunity. For what is a natura mode of defence in one country may be artificiall produced in another, or at least so nearly approache as to give great protection; and by the knowledge thus obtained those predisposing causes and circumstances which favour its propagation can be lessened or removed. The evidence, therefore, of anyone who has practised the medical profession, and who has lived for many years in a land so favoured, with reference to this disease, that nature has made it practically innocuous there, and who has at the same time had considerable clinical experience not only in general practice but in the charge of a public hospital should be of some service in this inquiry. I have lived in Pietermaritzburg, the capital of Natal, for 26 years, and during the whole of that time I have been in charge of its public hospital, known as Grey's Hospital. I have also been the greater part of that time medical officer to the corporation of Pietermaritzburg and have thus been brought into intimate relations with all sections of its inhabitants and have had its local conditions, socially and physically, constantly under consideration with reference to public health.

Pietermaritzburg is situated in the middle of the colony, about 40 miles from the sea in a direct line, at an altitude of 2200 feet. It is built at the foot of the southern spur inclosing the Zwaart Kop valley and is therefore in a very dry and sheltered situation. Its population numbers 30,000 of whom about half are coloured and consist of natives (that is, Zulu Kaffirs), Indians, and people of mixed races, the other half being Europeans. This city has nominated me its delegate to this Congress. Having thus presented my credentials I will proceed to describe the climate and topography of Natal and attempt to show how local conditions have modified the severity of tuberculosis in that colony.

Natal is part of south-eastern Africa, somewhat diamond-shaped, having a coast line of about 200 miles north of St. John's river and an area of about 20,851 square miles. It has a mixed population, being made up of 60,000 Europeans, 1,000,000 Zulus, and 50,000 Indians. Three such races, wholly dissimilar in habits, origin, and religion, present a diversified field for observation with reference to the prevalence of any disease and cannot but be instructive with regard to tuberculosis, from which deductions possibly can be made as to what locally tends to check the disease and what common boon these totally different races enjoy [illegible] appears to give each an immunity from its attack.

---

[1] A paper communicated to the British Congress on Tuberculosis: Section II., Medical, including Climatology and Sanatoria.

Natal is the last portion of healthy South Africa [illegible] the Drakensberg range. The healthiness of the eastern coast of Africa, from Cape Town to where Natal ends, depends upon the situation of the Drakensberg mountains. This range begins at Table Mountain behind Cape Town and as a guardian to human health ends at St. Lucia Bay in Zululand. After it passes St. Lucia Bay the range extends far north into the continent of Africa, but from St. Lucia northwards it ceases to be a factor in the preservation of health as far as human beings are concerned; indeed, it becomes a potent means of rendering the country almost uninhabitable to Europeans, thus forming a vast region where wild and savage beasts may be preserved, to await their own epoch for disappearance. Be that as it may, the Drakensberg range from Cape Town to St. Lucia Bay secures a good climate to that portion of the African continent and defends it from malaria. But north of St. Lucia Bay it causes such a condition of soil-saturation as to form a developing ground for the parasite of malaria, of such vast extent as to render hopeless all human means of making it healthy. That the same mountain range should be the guardian of health in one region and in another be the cause of the country being almost uninhabitable needs some explanation; and as it will help to throw more light on the physical features and condition of the healthy district which I am considering some further reference must be made to it. The Drakensberg range from Table Mountain at Cape Town runs north-east, following the coast line to St Lucia Bay for a distance of nearly 1000 miles, the last 200 of which form Natal. At St. Lucia Bay the mountains tend to the west, leaving the coast and gradually drawing inland, having an ever-increasing plain between the foot of the mountains and the sea. The result of this configuration is roughly to divide the eastern littoral of Africa into healthy, non-malarial, and unhealthy, malarial districts, St. Lucia Bay being the dividing point.

During the spring and summer, on the eastern coast of Africa, from Port Elizabeth northwards, the south-west wind blows on to the land, laden with moisture from the ocean; and it is from this source that Natal receives its plentiful supply of rain from October to May, which cools and fertilises the country, keeps it healthy, and renders it a suitable place for European settlement. On the other hand, it is also this rain-laden wind which, north of St. Lucia Bay, makes Africa, by the operation of the mountains, practically uninhabitable from malaria. The foot of the Drakensberg, from Table Mountain at Cape Town to the lagoon known as St. Lucia Bay, is practically conterminous with the sea. On this account moisture condensing into rain and falling on the range runs directly into the sea, there being no flat land intervening to receive it. Natal being part of the side of that range, its rainfall descends on the eastern watershed of the Drakensberg and runs directly into the Indian Ocean, leaving the earth and air dry and cool. But from St. Lucia Bay, north-east of Natal, on account of the westward tend of the mountains, the rain which falls on the Drakensberg, increasing from occasional thunderstorms in Natal to a torrential downpour as the mountains pass north and approach nearer to the equator, does not flow directly into the sea, but is in a great part absorbed by the ever-increasing plain which, as the mountain foot recedes westward, interposes between the range and the sea. From this vast plain arises the malaria which makes Eastern Africa uninhabitable for Europeans. The non-saturation of the soil of Natal is not only demonstrated by these physical features but also by the fact that it is completely free from malaria, which it certainly would not be if it was in the least water-logged. It is necessary thus fully to explain the origin of the malaria north-east of Natal to make it clear that the soil of that colony is dry and its surface and sub-soil well drained. Anyone watching a rainstorm forming in Natal would be surprised to notice that the clouds seem to come from the interior, where nothing but the waterless continent of Africa exists, the apparent marvel being that rain seldom or never seems to come from the direction of the sea. Great masses of cloud can be seen forming on the Drakensberg or rapidly condensing and passing down the spurs of that range to the ocean, the moisture from which the rain is formed having passed eastward with the south-west wind until stopped and condensed by the mountain range in the interior, often with the grand electric disturbance so well known as the Natal thunderstorms.

The Drakensberg range runs north-east through Natal, [illegible] spurs south-east, practically, if [illegible] their origin in the [illegible] easterly directly to [illegible] greater part of their [illegible] producing wind of th[illegible] gusts of hot dry wind from the north-east. The latter, being evidently obstructed currents, blow directly on the earth, thus having the power of raising the dust, and are the cause of the dust-storms of Natal which are the most trying feature in the climate; but, fortunately, they are not of frequent occurrence, being most prevalent in August, September, and occasionally later in the summer, but occur on the whole not oftener than a dozen times in the year. Apart from the power they have of raising the dust, which away from the main roads and towns is very limited, they are not unhealthy. The atmospheric obstruction is of short duration, the hot wind seldom lasting more than a day, and often only a few hours, and is always followed by the cool rain-carrying south-west current which, being parallel with the earth's surface, does not raise the dust, and being [illegible] denses into rain, refreshing a[illegible] will be seen that the prevalent [illegible] valleys [illegible] north side of the valley, on which beat directly the wind and rain from the south-west and which is protected from the dry, hot, north-east winds. On the other hand, the south side of the valley, with its north-east aspect, is dry and sheltered from the rain-storms and is open to the hot wind. The result on the vegetation of these valleys is remarkable; the bush almost invariably occupies the south-west aspect of the upper ridges of the northern slopes and the grass is rank and sour, all directly the result of exposure to the south-west rains and being protected from the hot north-east winds; the ground retains moisture throughout the year in a sufficient degree to enable both grass and bush not only to grow but to resist the effects of the grass fires. So marked is this arrangement of the vegetation that the bush stops in a sharp and straight line along the tops of the hills as if it had been so planted by the hand of man and the grass becomes shorter and sweeter, the exposure to rain being less, and the drying greater. Deep in the valleys on the south side, well open to the north-east so as to escape the heat of summer, and high enough from water to avoid the cold in winter, which is always associated with water, is the best situation for a residence. Such is the situation in which Pietermaritzburg is built, and the choice of the site shows the knowledge of the country possessed by its Dutch founders. This rough landscape and weather guide apply more particularly to the highland and midland districts of Natal. Those seeking health there, suffering from, or threatened with, pulmonary tuberculosis, and who may wish to combine farming with that pursuit, must never forget that shelter is the great desideratum for man and beast in South Africa.

Natal, being practically the side of a mountain, possesses three fairly distinct climates and has as a result a very wide range of products. The climate of the coast is that of a warm and semi-tropical district; humid during the spring and summer, from September to May, on account of its proximity to the sea and the prevalence of the sea-breeze during that season [illegible] throughout the year [illegible] autumn and winter, [illegible] bright, dry, and free from frost. In this district tropical fruits grow well—oranges and other citrus fruits, mangoes, pineapples, bananas, guavas, and such productions as sugar, tea, coffee, maize (known locally as "mealies"), millet (or "Kaffir corn"), and tobacco. It is not a good cattle country, but cattle can be bred there; sheep do not thrive; poultry do well; and, for South Africa, it is thickly populated by natives and Indians. But it is not a region in which Europeans flourish. In the midlands the climate at an altitude of from 2000 to 3000 feet is very healthy and suitable for European settlement. The rainfall is about 30 inches per annum and the mean temperature is considerably lower than the coast. The atmosphere is much drier and there is a distinct fall in the temperature at night, which is refreshing and invigorating and induces sound sleep, the absence of which is perhaps the most debilitating characteristic of the coast, and during the winter frost at night is of common occurrence. The ground from even a step further and demand that the udder in all cows from which milk is taken for human food shall be in a perfectly normal condition.

The main causes of tuberculosis in cows are notorious: close confinement in ill-ventilated, badly-lighted, ill-constructed and dirty cowsheds—defects all as easy to remedy as is removal from the cowshed of the obviously [illegible] animal before it can cause infection of the rest. [illegible] of Liverpool about 26,000 gallons of milk are consumed every day; one-half of it comes from cows (about 6000 in number) kept within the city, the other half comes from cows kept in the country and is sent in by rail. Within recent years that part of the milk-supply which comes from cows kept within the city has been practically free from tuberculosis. This has been brought about by the sanitation of the cowsheds, adequacy of air, light, and cleanliness, by systematic and frequent inspection of the cows by qualified inspectors with veterinary help, and by frequent bacteriological analysis of the samples of milk; these are the measures which have effected this end. I do not say that out of the 6000 cows in the city there is not a single one affected with tubercle, but merely that there are few with such form of tuberculous disease as would be likely to contaminate the milk-supply.

These methods and this system of inspection were not initiated without difficulty and opposition. There is no opposition now; every person acquiesces in advantages which have been gained. But there is another aspect to the question. Only one-half of the quantity of milk consumed in Liverpool is supplied from the city, the remaining half comes from the country districts. But surely, it may be said, if the cows kept in the cowsheds within a great and populous city are healthy, those coming from the sunny meadows of the country, with their fertile pastures and ample land, are free also. Unfortunately, experience does not bear this out; the *milk sent in from the country is more frequently tuberculous.* Thus, out of 422 town samples examined during 1899 and 1900 five were tuberculous, being less than 1 per cent.; but out of 490 country samples taken during the same period 20 were tuberculous, being a trifle over 4 per cent. How can we protect ourselves against this? A special Act of Parliament applying to a few great towns, including Liverpool, gives special powers to exclude from the city, under a penalty, the milk coming from the country cowsheds in which tuberculous cows are kept under dirty and insanitary conditions. But if it is difficult to deal with and to supervise the supply within our own city, it is evidently both costly and difficult to maintain a staff to send under the special Act of Parliament to the insanitary and tubercle-ridden cowsheds of the country cowman, but having overcome these difficulties the broad national question comes in, for although we succeed in protecting ourselves what happens with regard to the diseased cows and the diseased milk? The dealer refrains from sending diseased milk to the protected city, but what is there to prevent him from sending his milk for sale and consumption to a district where no special Act of Parliament exists to enable the community to protect itself or from selling his diseased cows to a dairyman in another locality? This is not the way to secure a supply of milk from herds free from tuberculosis, but there can be little doubt that the action of the great cities will not only protect themselves but will to a certain extent protect the country districts also and will strengthen the hands of rural sanitary authorities. No doubt the great cities are financially better able to protect themselves; they have their larger and more costly staff, they have their bacteriological laboratories, their veterinary and medical officers, but at best they are but valuable allies to the rural sanitary authorities, and these, after all, must take their own action, since the protection the cities afford them is an indirect vicarious one and, as in cases which I have alluded to, there is nothing to prevent the cowkeeper from sending his diseased produce to rural districts after he has been prohibited from sending it to the great cities. Furthermore, the undoubted decline in the proportion of tuberculous milk sent in from the country may really mean that a larger proportion is consumed elsewhere. The subject is quite important enough for a Government department—e.g., the Local Government Board—to take in hand and appoint a special staff to supervise the milk-supply and all appertaining to it throughout the country.

I have no hesitation whatever in saying that it is quite possible to ensure that the milk-supply shall come from cows [illegible] from tuberculosis. Difficulties from ignorance, obstruc- [illegible] sition may be taken for granted, but these must be overcome, and the cowkeeper will learn in time that his own interests are identical with those of his customers, and by keeping healthy cows in a sanitary condition he will be a gainer in every way. It is only right to say that during last year samples of milk taken at the railway stations on arrival from the country do not appear to be more [illegible] tuberculous than the samples taken from the [illegible] may indicate one of two things: either a general improvement in the country cowsheds under the stimulus of city action, or, as in more cases than one which have come under my notice, dairymen who have been detected in sending in tuberculous milk have refrained altogether from sending milk to Liverpool and now send their milk elsewhere. These are points not to be lost sight of.

NATURAL IMMUNITY FROM TUBERCULOSIS IN NATAL, SOUTH AFRICA.[1]

By JAMES F. ALLEN, M.D. R.U.I.,

DELEGATE FROM PIETERMARITZBURG, NATAL, SOUTH AFRICA.

SITUATION, TOPOGRAPHY, AND CLIMATE OF NATAL.

IN considering the means whereby the disease known as "tuberculosis" may be repressed climatology must always take an important place, it being a matter of common notoriety that in certain parts of the world, under certain conditions of climate, topography, and social relations, this disease is a scourge which almost threatens the existence of the human race; and again in other regions, and under different circumstances, it seems to have lost its power of injuriously affecting man, though in some degree it may be known to exist locally. How the human race can exist in any country where this disease is known also to be, and be practically free from its affects, is a question so interesting, important, and instructive that every effort should be made to explain such immunity. For what is a natural mode of defence in one country may be artificially produced in another, or at least so nearly approached as to give great protection; and by the knowledge thus obtained those predisposing causes and circumstances which favour its propagation can be lessened or removed. The evidence, therefore, of anyone who has practised the medical profession, and who has lived for many years in a land so favoured, with reference to this disease, that nature has made it practically innocuous there, and who has at the same time had considerable clinical experience not only in general practice but in the charge of a public hospital should be of some service in this inquiry. I have lived in Pietermaritzburg, the capital of Natal, for 26 years, and during the whole of that time I have been in charge of its public hospital, known as Grey's Hospital. I have also been the greater part of that time medical officer to the corporation of Pietermaritzburg and have thus been brought into intimate relations with all sections of its inhabitants and have had its local conditions, socially and physically, constantly under consideration with reference to public health.

Pietermaritzburg is situated in the middle of the *colony*, about 40 miles from the sea in a direct line, at an altitude of 2200 feet. It is built at the foot of the southern spur inclosing the Zwaart Kop valley and is therefore in a very dry and sheltered situation. Its population numbers 30,000 of whom about half are coloured and consist of natives (that is, Zulu Kaffirs), Indians, and people of mixed races, the other half being Europeans. This city has nominated me its delegate to this Congress. Having thus presented my credentials I will proceed to describe the climate and topography of Natal and attempt to show how local conditions have modified the severity of tuberculosis in that colony.

Natal is part of south-eastern Africa, somewhat diamond-shaped, having a coast line of about 200 miles north of St. John's river and an area of about 20,851 square miles. It has a mixed population, being made up of 60,000 Europeans, 1,000,000 Zulus, and 50,000 Indians. Three such races, wholly dissimilar in habits, origin, and religion, present a diversified field for observation with reference to the prevalence of any disease and cannot but be instructive with regard to tuberculosis, from which deductions possibly can be made as to what locally tends to check the disease and what common boon t [illegible] appears to give each [illegible]

---

[1] A paper communicated to the British Congress on Tuberculosis, Section II., Medical, including Climatology and Sanatoria.

Natal is the last [illegible] the Drakensberg range. The healthiness of the eastern coast of Africa, from Cape Town to where Natal ends, depends upon the situation of the Drakensberg mountains. This range begins at Table Mountain behind Cape Town and as a guardian to human health ends at St. Lucia Bay in Zululand. After it passes St. Lucia Bay the range extends far north into the continent of Africa, but from St. Lucia northwards it ceases to be a factor in the preservation of health as far as human beings are concerned; indeed, it becomes a potent means of rendering the country almost uninhabitable to Europeans, thus forming a vast region where wild and savage beasts may be preserved, to await their own epoch for disappearance. Be t [illegible] from Cape Town to St. [illegible] that portion of the Af[illegible] malaria. But north of St. Lucia Bay it causes such a condition of soil-saturation as to form a developing ground for the parasite of malaria, of such vast extent as to render hopeless all human means of making it healthy. That the same mountain range should be the guardian of health in one region and in another be the cause of the country being almost uninhabitable needs some explanation; and as it will help to throw more light on the physical features and condition of the healthy district which I am considering some further reference must be made to it. The Drakensberg range from Table Mountain at Cape Town runs north-east, following the coast line to St. Lucia Bay for a distance of nearly 1000 miles, the last 200 of which form Natal. At St. Lucia Bay the mountains tend to the west, leaving the coast and gradually drawing inland, having an ever-increasing plain between the foot of the mountains and the sea. The result of this configuration is roughly to divide the eastern littoral of Africa into healthy, non-malarial, and unhealthy, malarial districts, St. Lucia Bay being the dividing point.

During the spring and summer, on the eastern coast of Africa, from Port Elizabeth northwards, the south-west wind blows on to the land, laden with moisture from the ocean; and it is from this source that Natal receives its plentiful supply of rain from October to May, which cools and fertilises the country, keeps it healthy, and renders it a suitable place for European settlement. On the other hand, it is also this rain-laden wind which, north of St. Lucia Bay, makes Africa, by the operation of the mountains, practically uninhabitable from malaria. The foot of the Drakensberg, from Table Mountain at Cape Town to the lagoon known as St. Lucia Bay, is practically conterminous with the sea. On this account moisture condensing into rain and falling on the range runs directly into the sea, there being no flat land intervening to receive it. Natal being part of the side of that range, its rainfall descends on the eastern watershed of the Drakensberg and runs directly into the Indian Ocean, leaving the earth and air dry and cool. But from St. Lucia Bay, north-east of Natal, on account of the westward tend of the mountains, the rain which falls on the Drakensberg, increasing from occasional thunderstorms in Natal to a torrential downpour as the mountains pass north and approach nearer to the equator, does not flow directly into the sea, but is in a great part absorbed by the ever-increasing plain which, as the mountain foot recedes westward, interposes between the range and the sea. From this vast plain arises the malaria which makes Eastern Africa uninhabitable for Europeans. The non-saturation of the soil of Natal is not only demonstrated by these physical features but also by the fact that it is completely free from malaria, which it certainly would not be if it was in the least water-logged. It is necessary thus fully to explain the origin of the malaria north-east of Natal to make it clear that the soil of that colony is dry and its surface and sub-soil well drained. Anyone watching a rainstorm forming in Natal would be surprised to notice that the clouds seem to come from the interior, where nothing but the waterless continent of Africa exists, the apparent marvel being that rain seldom or never seems to come from the direction of the sea. Great masses of cloud can be [illegible] Drakensberg or rapidly condensing [illegible] ocean, the [illegible] that range to the [illegible] is formed having passed eastward with the south-west wind until stopped and condensed by the mountain range in the interior, often with the grand electric disturbance so well known as the Natal thunderstorms.

The Drakensberg range runs north-east through Natal, [illegible] its spurs south-east, practically, if [illegible] to the main range. Rivers having [illegible] lands run down its valleys in an easterly direction directly to the sea, rapid mountain streams for the greater part of their course. The prevailing south-west rain-producing wind of the summer is occasionally interrupted by gusts of hot dry wind from the north-east. The latter, being evidently obstructed currents, blow directly on the earth, thus having the power of raising the dust, and are the cause of the dust-storms of Natal which are the most trying feature in the climate; but, fortunately, they are not of frequent occurrence, being most prevalent in August, September, and occasionally later in the summer, but occur on the whole not oftener than a dozen times in the year. Apart from the power they have of raising the dust, which away from the main roads and towns is very limited, they are not unhealthy. The atmospheric obstruction is of short duration, the hot wind seldom lasting more than a day, and often only a few hours, and is always followed by the cool rain-carrying south-west current which, being parallel with the earth's surface, does not raise the dust, and being moisture-laden soon condenses into rain, refreshing and cooling the earth. Thus it will be seen that the prevalent winds in Natal blow across the valleys, not up or down them, the result being that in almost every valley there is an exposed and sheltered side and a point of greatest rest, the exposed being the south-west face on the north side of the valley, on which beat directly the wind and rain from the south-west and which is protected from the dry, hot, north-east winds. On the other hand, the south side of the valley, with its north-east aspect, is dry and sheltered from the rain-storms and is open to the hot wind. The result on the vegetation of these valleys is remarkable; the bush almost invariably occupies the south-west aspect of the upper ridges of the northern slopes and the grass is rank and sour, all directly the result of exposure to the south-west rains and [illegible]-east winds; the ground re[illegible]ar in a sufficient degree to [illegible] only to grow but to resist the effects of the grass fires. So marked is this arrangement of the vegetation that the bush stops in a sharp and straight line along the tops of the hills as if it had been so planted by the hand of man and the grass becomes shorter and sweeter, the exposure to rain being less, and the drying greater. Deep in the valleys on the south side, well open to the north-east so as to escape the heat of summer, and high enough from water to avoid the cold in winter, which is always associated with water, is the best situation for a residence. Such is the situation in which Pietermaritzburg is built, and the choice of the site shows the knowledge of the country possessed by its Dutch founders. This rough landscape and weather guide apply more particularly to the highland and midland districts of Natal. Those seeking health there, suffering from, or threatened with, pulmonary tuberculosis, and who may wish to combine farming with that pursuit, must never forget that shelter is the great desideratum for man and beast in South Africa.

Natal, being practically the side of a mountain, possesses three fairly distinct climates and has as a result a very wide range of products. The climate of the coast is that of a warm and semi-tropical district; humid during the spring and summer, from September to May, on account of its proximity to the sea and the prevalence of the sea-breeze during that season. The average mean [illegible] throughout the year in th[illegible] autumn and winter, from [illegible] bright, dry, and free fro[illegible] fruits grow well—oranges [illegible] pineapples, bananas, guavas, and such productions as sugar, tea, coffee, maize (known locally as "mealies"), millet (or "Kaffir corn"), and tobacco. It is not a good cattle country, but cattle can be bred there; sheep do not thrive; poultry do well; and, for South Africa, it is thickly populated by natives and Indians. But it is not a region in which Europeans flourish. In the midlands the climate at an altitude of from 2000 to 3000 feet is very healthy and suitable for European settlement. The rainfall is about 30 inches per annum and the mean temperature is considerably lower than the coast. The atmosphere is much drier and there is a distinct fall in the temperature at night, which is refreshing and invigorating and induces sound sleep, the absence of which is perhaps the most debilitating characteristic of the coast; and during the winter frost at night is of common occurrence. The ground from the sea rises rapidly, ridge after ridge, into apparently confused hills and valleys, until, within 40 miles of the sea, the altitude of the whole country has risen to over 2000 feet. The landscape is open and undulating, well watered, and almost free from bush. Horses, cattle, and sheep thrive; mealies, millet, potatoes, oat forage, green barley, peas, beans, and tobacco grow well; citrus fruits of all kinds, and apples, pears, peaches, and plums flourish. It is the home of many European farmers, but it is by no means fully occupied and would support a much larger population than it carries at present, and there can be no doubt but that when South Africa is thoroughly known it will do so. Within it are high, and at the same time sheltered, districts peculiarly suited to persons threatened with, or suffering from, tuberculosis; where in the case of actual disease recovery may take place or strength may be maintained by continued residence, and where feebleness of constitution, unless disease exists, may be secured from invasion. The high land, up to the foot of the peaks of the Drakensberg, from 3000 to 6000 feet above the sea, is an open, rolling, grassy country, covered with sweet short herbage, on which stock of all kinds thrive. Indeed, it is the stock country of Natal—for horses, cattle, and sheep there is no better district in South Africa. The atmosphere in summer is cool and dry and cold and frosty in the winter. During the spring and summer, from September to May, thunderstorms and hail are not uncommon and are often destructive to fruit and crops; but during the winter, from May to September, no rain falls. The district, however, is so well supplied with running streams that nothing but the grass suffers from drought. Then, indeed, the country is dry and the grass is parched; but for all that cattle reared in the district can find subsistence until the spring grass appears, which is always early. As, however, the breed of horses and cattle has improved, and lands become inclosed, farmers have been compelled to provide some winter food. Grass cut on the veldt and made into hay, with very little else, is found to be sufficient. This district will in the future be not only the principal dairying country, but it will produce sufficient meat to supply the whole colony, for there the largest and heaviest breeds of cattle can be reared. European fruit of all kinds thrives. There are to be found the most successful orchards in the colony. Mealies, wheat, millet, oats, barley, turnips, peas, beans, and potatoes grow well, and human health is excellent. Thus it will be seen that the climate in Natal is very dependent upon altitude, but though it is thus varied in the main it consists of two seasons—the summer, in which there is rain, and the winter, in which there is none. During the summer the heat is often trying, but in the midlands and highlands it is greatly relieved by the fall in the temperature at night. During the cold months, from the end of April to September, the whole atmosphere of the country, from the sea to the summit of the Drakensberg, is cool, dry, and still. But no description of the climate can adequately convey to the mind the exhilaration of spirits and body produced by the certainty almost of pleasant weather and unfailing sunshine, with the possibilities it affords of open-air life which the inhabitants lead.

If we search for tubercle in Natal we shall get some instructive information if in the first instance we seek for it among cattle born and reared on the veldt of the colony. The cattle districts of Natal are the midland and highland terraces of the Drakensberg, especially the latter, at an altitude of from 2000 to 6000 feet above the level of the sea. Though the highlands are the best cattle-breeding districts and the largest and finest breeds can be reared there, being comparatively free from ticks, red water, and other pests which retard the success of cattle-farming elsewhere, as yet it is in the midlands that the greatest number of cattle are to be found, the highlands being but sparsely inhabited either by natives or Europeans and the midlands being thickly populated by natives who choose these sheltered districts on account of the mild climate, where they can grow mealies, millet, and tobacco in profusion and will not be exposed to sharp cold in winter as they would be in the higher altitudes. Here also their cattle get through the winter better, their owners not being put to the necessity of providing special food and shelter for them, as cattle there can, under normal conditions, find sufficient food on the veldt and shelter from the wind all the year round. The natives must have been well aware of the superior character of the country under the ridge of the Drakensberg for maintaining flocks and herds, if from nothing else, by the fact that during the spring and summer, before Europeans had settled in this district, the veldt was covered with game—antelopes of many different kinds in thousands and great herds of quagga; but all its recommendations sank to nothing in comparison to the inducements offered by the midlands, and to the fear that the great Zulu possessed for the little Bushman with his bow and poisoned arrows. In former times, before the Bushman was exterminated by Europeans, this weird race of savage mountaineers dominated this region and drove the Zulus from the sweet grass of the highlands. The last spurs of the Drakensberg were the home of the Bushmen. Here in the caves and rocks they could lurk in safety and from these heights they could survey the whole country spread out before them; and they had to hand the latest news of importance, as far as they were concerned, in those strange but life-like figures and drawings on the walls of caves and the protected faces of cliffs, whereby one roving band could convey to another the dangers and benefits to be found in each locality. Cattle-thieves by nature, the country offered them every facility for indulging the habit. Stolen cattle once in the defiles of the mountains were lost to their owners, and if overtaken before they reached their refuge with their poisoned arrows the Bushmen were always able to make a good defence against their pursuers. No wonder that the cattle-loving Zulu gave them a wide berth and even looked upon them with superstitious fear. This is the simple explanation of the uninhabited condition of the highlands of Natal on the advent of Europeans, and clears that part of the country from the least suspicion of unhealthiness. The midlands were and are the home of the Zulu. Here he possessed, before the rinderpest swept over the country, perhaps a million head of cattle—small, hardy, Zulu cattle suitable to the country. These animals, and indeed those belonging to Europeans, may with truth be described as wild cattle; a very few were tame enough to submit to being milked, but otherwise they were as free as the buck; they lived in a natural state, unaffected in any way by artificial surroundings, and whatever their state of health might be, it would be the reflex of the local natural condition of the country in which they were reared. If that land had a natural tendency to develop any disease which would affect cattle, then undoubtedly these cattle must suffer from it, as nothing was done by man to protect them; the country, too, being practically unfenced, they were fully exposed to contagion. Thus it was that rinderpest in a few weeks swept through the land and for the same reason lung-sickness (pleuropneumonia) devastates whole districts. Therefore the condition of the veldt cattle with reference to tubercle should be an indisputable piece of evidence as to the prevalence of that disease in the country. As the greatest number of cattle are to be found in the midlands, which experience suggests are not so likely to be as free from tuberculosis as the highlands, the field of inquiry cannot be said to be selected for the purpose of coming to a favourable conclusion. The result of observation and experiment, as far as it has gone in Natal, is to prove that the wild cattle—that is, the locally bred cattle running on the veldt—are free from tubercle. Though such an immunity goes far to prove that the disease is innocuous to animals living in a natural state on the veldt, yet it does not prove that tubercle does not exist in the colony. That it does exist there is easily demonstrated by examining dairy cattle. If healthy wild cattle are caught, handled, confined in cowhouses and fed, milked, used, and treated as dairy cattle, they seem to lose their immunity against tubercle, they may become affected with it and may suffer from it in the same degree as dairy cattle in England. The immunity possessed by wild cattle in Natal is therefore not directly due to climate. This is an important point to establish for those who have to contend against the disease in climates which are supposed to be favourable to its development.

Again, take the well-known history of another animal, the monkey, with reference to this disease. These animals, captured in a healthy condition, carried to Europe, and confined in cages, even though the greatest care is taken that their surroundings are healthy and the air they breathe is warmed, yet they die in great numbers from tuberculosis. Neither the cow nor the monkey eat meat or drink milk and could not be affected from their food, yet neither a warm climate nor food free from tubercle was sufficient to protect them. Both fall victims to the disease on losing immunit and both in common suffer this loss by being subjected t a complete change in environment and to confinement There being ample evidence to prove that tubercl bacilli are to be found everywhere, the tissues o these animals must have been able to resist the growth of the bacillus in their wild state Contact is therefore not the cause of the invasion, that must have taken place frequently before The change is in the animal itself—it has become vulnerable Exactly the same set of events occur with reference to the bacillus of putrefaction When death takes place immunity from its invasion disappears, it develops in the body and decomposition follows, exposure to the bacillus being the same before as after death Something has died in the cow and the monkey on their confinement which permits of the bacillus of tubercle developing What, then is this natural immunity which is thus capable of resisting the growth of a bacillus under one set of circumstances but is lost under another? It is evidently the result of bodily perfection and is the product of selection It is very different from scientific immunity, though its results while it continues, are the same It does not last as long as that caused by vaccination against small pox, but natural immunity, being dependent on selection and perfection, is more to be desired than scientific immunity, which has nothing to do with either, and can be established in the weak and diseased, while that of nature can only come after the weak have been made strong and the diseased are cured, and is thus always salutary, whether it is applied to the individual or to a race or species If we can discover nature's secret and adopt it or as much of it as climate and circumstances will permit, we shall be advancing undoubtedly on the right road We may thus in a great measure, supersede the necessity for the discovery of scientific methods for establishing individual immunity which though extremely important from a personal point of view, are essentially destructive as they tend to preserve the unfit with the fit, and which with reference to this special disease (tuberculosis) may not be attainable

That such natural immunity does exist, to a greater or less extent, against the invasion of almost every specific bacillus, no one with any clinical experience will deny Apparently such immunity differs with the bacillus one set of circumstances making the body liable to the invasion of that of tubercle, another to that of tetanus and a third to that of putrefaction, and so on but these three bacilli in relation to the human body have much in common and apparently demonstrate this theory of natural immunity very clearly The bacilli of all three seem to exist everywhere, and in any place a healthy living body can be made immune against their natural invasion, while, on the other hand, means can be found to cause it in the ordinary manner to become affected by all three The law seems to be that when immunity is lost invasion follows The futility, then of fighting such bacilli becomes clear as a side issue in the campaign it is right and desirable but as a central idea it is wrong and misleading For instance, inspecting food for tubercle is not of much use if the consumer is permitted to live in an abnormal environment under such circumstances as tend to cause loss of natural immunity—invasion and growth of the bacillus must follow whether it enters by food or otherwise The absence of tubercle from the food of the cow and the monkey does not protect th [illegible] ence of tubercle from the food of [illegible] city slum will not save them At [illegible] cillus is beginning at the wrong end of the problem Greater attention should be paid to that which is attacked than to that which attacks

Human beings in Natal are almost as free from tubercle as its cattle Tuberculosis in one or other of its forms is to be met with, but the number of such cases is so small, and as the disease shows no signs of increasing as a local product its existence is more a warning than a danger Tuberculous disease of the glands or of the membranes of children is as rare as pulmonary disease in adults and tubercle of the skin is very uncommon When therefore 60 000 people are exempt from the well known ravages of such a complaint, something must have developed in them a natural immunity which is capable of resisting the growth of the bacillus The presence of the disease among the people in the few cases which occur shows that it is immunity, not freedom from exposure which keeps the disease in subjection What, then are the conditions under which these people live which have developed this immunity? Undoubtedly they are to be found in the open air life which the benign climate and health- country have made possible [illegible] tained resistance in cattle and [illegible] power in man. The best Nata [illegible] is but a shelter from the sun and rain It is, as a rule, only one storey with matchwood ceilings and well ventilated roof The people sleep with the windows open at night Each family has a house to itself and often a piece of garden. There is no overcrowding and no one is deprived of fresh air and light The towns have no echoing streets of three- and four storey houses which exclude light and air from each other and the street between There are no flats or slums There is in Natal a tendency to abandon house life The love of reading, essentially a house pastime, is not a characteristic of the country Open air games, riding, bicycling and out-of-door occupations of all kinds are much sought after In the towns business will be suspended for a cricket or football match of any note All the shops must be shut and this only a very foolish trader would attempt to resist In the cities never since the Greek republics has there been a community so given to gossiping on public affairs in the open air When anything of interest stirs the public mind the whole population turns out to discuss the matter in the streets All the inquirer after public opinion has to do is to pass from group to group, and he will quickly know how the public leans So well understood is this that members of the Government well known public men, newspaper editors, and politicians of all kinds can be met in the highways and byways gathering information In no part of the world is the ' man in the street' such a reality or so supreme

So mild is the climate that people can sleep in the open air at night without risk A favourite form of picnic is to camp out in tents for a week or a fortnight at a time, and a blanket or less is consider [illegible] at night There are no [illegible] known It may not be [illegible] of the whole world in such a manner, but those who so live are certainly more free from disease of all kind more especially tubercle than the hard working, overcrowded populations of European cities

The Zulu natives of Natal are a stalwart, healthy race, husbandmen by calling and are in possession of a large proportion of the colony is theirs by right They are a prosperous and happy people The uncivilised Zulus can be said to be free from tuberculosis in all its forms, but with civilisation the disease appears The Kaffir inhabitants follow the rôle of the cow and the monkey in that respect. Confine them, alter their diet make them wear clothes, and the less robust soon lose their immunity and fall victims to the disease There is a high mortality among the children of the wild Kafirs, probably three times as great as among Europeans but it is not from tuberculosis As with Europeans, so among the uncivilised Kaffirs an occasional case of pulmonary tuberculosis is to be found Tubercle of the skin is rarely seen The diet of these people in their wild state is quite different from that of Europeans In Natal the latter eat more meat than would be considered wholesome in Europe, and is even less suitable to a climate like Natal The Zulu Kaffir lives in his natural state on maize, called locally "mealies," made into porridge or cooked in some other way, and curded milk, but the staple article of his food is Kafir beer or *ishwala* a thin fermented porridge made from millet (Kafir corn) This Kaffir beer leads to many a faction fight Occasionally this diet is varied with a substantial meal of meat *Ishwala* is prepared by allowing millet to sprout, thus malting it It is then dried and stored for use and at any time can be made into beer by a very simple process It is first pounded into a rough meal, put into calabashes, into which is poured a sufficient quantity of water, and the whole is allowed to ferment, during which time it is stirred, skimmed, and kept at a temperature which aids the process When it has acquired the right alcoholic strength, which is about that of lager beer, it is fit for consumption It is given to children a few weeks old and does not disagree if sound and given with judgment It is easily digested as most of the starch in the grain has been changed by fermentation into glucose It has a sour, pungent smell. Its taste is tart, pleasant, and agreeably refreshing It is most sustaining but it is thickish and reddish-yellow in colour It possesses the power of dilating the stomach after it is drunk by the quantity of carbonic acid gas which it evolves, a most valuable property where there is a tendency to contraction of that organ as takes place in many wasting diseases especially in phthisis, where contraction of the stomach, and consequent inability to take food, with failing appetite tends greatly to hasten a fatal result. I have used it freely in wasting diseases of different kinds and have always found it most invigorating I believe it would be a valuable article of diet for the purpose of sustaining strength and combating waste in phthisis, not only on account of its digestibility but also for its power of dilating the stomach. It contains a considerable quantity of alcohol which is quite capable of causing intoxication, but this alcohol is of such a digestible character that it does not cause organic disease nor does it demoralise as results from drinking European spirits; on the contrary, it helps to sustain and to invigorate. Certainly alcohol taken in that form, even though the quantity imbibed daily may be large, produces no predisposing tendency to tuberculosis. On the contrary, I think it would materially help in the curative treatment of that disease. The effect it has is greatly to increase the adipose tissue of the body. It is to the consumption of *tshwala* that the well-known obesity of Kaffir chiefs is due.

In reviewing the vital condition of the Kaffir race some allowance must be made for the fact that every Zulu who arrives at adult age is a "survival of the fittest," the weaklings having been weeded out; but though this secures to a great extent a vigorous people it does not prevent a failure of constitution under unfavourable conditions, with the loss of natural immunity against tubercle which allows the bacillus to grow in the body. During their wild existence they live a life which tends to maintain what selection has started. They have no cities and consequently there is no overcrowding. Their grass huts are about six feet high inside, just enough space for a tall man to stand upright. These are not lasting structures, being often destroyed and renewed—change of site for his residence being a Zulu's commonest recourse for protection when serious illness has attacked his family, and though he thus acts more from superstitious than hygienic motives the result is alike beneficial. Thus the houses do not become the home of all the disease-producing bacilli which have generation after generation affected the residents, as in the case of the old, disease-sodden dwellings of the poor of Europe. To the Kaffir, poor or rich, his hut is a friend, though it is but a shelter and a place to sleep in. To the poor of Europe their houses are often a deadly enemy.

The lithe, wiry figure of the Indian, clad in his bright-coloured clothing, is a familiar and picturesque object in the Natal landscape. 50,000 British Indians reside in the colony. They have been imported chiefly for field labour and are employed principally in the cultivation of sugar-cane on the coast, but though by far the greater number live there they have spread far into the interior and are to be found in every centre of population from Durban to Bulawayo. They belong to the labouring class in India and are for the most part low-caste Hindoos. Banyans—that is, Mahomedan traders from Bombay—have also found their way to Natal and many have acquired considerable wealth. Residence in Natal causes the Hindoo labourer to improve greatly in physique which is especially noticeable in the second generation. This is the result of the climate, the country, and the food, Natal being in all three respects for him a change for the better. The Hindoos are industrious and healthy. Their houses are grass-covered huts, or shanties covered with corrugated iron or the tin of packing-cases. They are almost vegetarians in diet, living principally on rice, mealies, peas, fruit, dried fish, clarified butter, and occasionally a little flesh—mutton, goat, or fowl. They are by no means a temperate people as far as the consumption of alcohol is concerned. They drink spirits freely, especially rum. They are practically free from tuberculosis in any of its forms. It is an exceptional thing to find an adult suffering from pulmonary tuberculosis, nor do children suffer from it in any other region, and tubercle of the skin is very rare.

Here, then, in Natal are two alien races, Europeans and Indians, differing in habits, customs, and food, from one another and from the native Zulus, but both in common with the native presenting the same aspect with reference to tuberculosis—almost entire immunity. The open-air life which each race lives seems to be the only common influence they enjoy which could account for it.

If the general hospitals in Natal are visited cases of phthisis will be, indeed, found among European patients, but almost invariably these are immigrants, mostly young men and in the last stage of the disease. Latterly the number of such persons visiting the colony in search of health has greatly increased and has caused attention to be paid to the matter by the Government so far that shipping companies have been asked not to give passages to persons in advanced consumption, but otherwise no serious attempt has been made to stop the entry of such cases into Natal. No country, however, will long consent to such an invasion, and if it is not checked and some discretion is not exercised in the selection of cases I feel sure that the colony will follow the example of New Zealand and refuse entry to persons suffering from tuberculosis. The great majority of the persons so suffering who have lately arrived in Natal are not only in a hopeless condition but destitute. Very many go with the hope that, the country being a British colony, they will be able to get employment, but as most are palpable victims of consumption no one will employ them and their failing strength soon makes work impossible. They then pass through many stages of hardship, until finally they find their way to the hospitals, where they are permited to remain till their death; but these institutions protest against receiving them as their limited funds are thus used in the treatment of hopeless cases which they should never have been called upon to admit. It is generally felt that the maintenance of such cases should be a charge on the country of their origin which they should never have been permitted to leave. If in the future Natal is to be used as a sanatorium for consumptives destitute persons must be sent there under some recognised system whereby they will be received and maintained in the colony until they are well enough to support themselves or until the end of their life. The present mode of casting them adrift is both inhuman and impolitic.

THE TREATMENT OF PHTHISIS AS A PREVALENT DISEASE IN HOLLAND.[1]

By Dr. R. de JOSSELIN de JONG.

WHEN the invitation sent by the committee of organisation of this Congress reached me, as one of the founders and the secretary of the society for organising sanatoria in Holland I was especially glad to be able to accept it because the movement is with us still in course of development, and I was convinced that for us beginners there could be much to be learnt here on this subject. Allow me, in a few words, as a contribution to a general survey about the organisation of sanatoria in Europe, to relate the state of affairs in Holland

We must not be looked upon as behind-hand because Holland is among the last of the countries to erect popular sanatoria. This has been caused by the historical succession of opinions as to how phthisis should be contended with. How long was it not believed that high mountain air was the first essential for a good health resort for consumptives? and to this day many are found who see the strongest therapeutic agency in a mountainous climate, in the influence of higher air. For some years a home for poor Dutch consumptives has existed in Davos Platz, started by private charity, but the idea that we *should build our own sanatoria* in the mother country—our low-lying Netherlands—has only been conceived in the last few years, after the experience gathered at home and abroad had taught us that the dogma of the mountain air therapy could be abandoned. Dr. Hamoch, our Nestor and president, Professor Kooyker and Dr. Wynhof, as well as others, have called repeated attention not only to the possibility, but to the urgent necessity, of founding popular sanatoria in our own country. What is being accomplished at Tuselbad, Laubbach, Halle, Rehburg, Bournemouth, Cheltenham, and other places can be accomplished with us, while it will be counted an advantage that the patients recover in the same climate in which they became ill. The change from sanatorium to their former life is less great if they have been treated in their own country.

In the beginning of the year 1897 about 20 men united to form a founding committee. Among them were the professors for internal diseases of all the four universities. This council has succeeded in awakening the interests of the country in their plans, and a society has been formed for the erection and provision of popular sanatoria for consumptives in Holland. 70 subdivisions were formed in different parts of the country with about 5000 members. H.M. the Queen-Mother graciously consented to become the patroness of the society. In the course of the first year 200,000 francs had been collected and the plans could be drawn up for the first sanatorium. The great question in our country was where the first sanatorium should be—on the sea-coast or in the interior? Professor Kooyker had already spoken on this subject at the Berlin Congress in 1899, and touched on the difficulties and advantages of both situations. Notwithstanding that, in proportion to the size of the country, our coast-line is a long one, it is very difficult to find a suitable spot for a so-called "seaside sanatorium." The exposure to west and north-west winds makes most of the places on the coast unsuitable, especially in winter. We decided to begin with an inland sanatorium, and we believe that we have found an excellent situation, for it in the east of the country—in the province of Overysel. It is, however, still most decidedly our purpose, when we are in a position to build a second sanatorium, to have it on the coast, as we are convinced that the strong, pure sea air will be a mighty power against phthisis; and although this air may not be suitable for more erethic constitutions, for less serious cases and for torpid tuberculosis it will, without doubt, be of the greatest advantage. This has been sufficiently proved to us by the beneficial effect a stay at the seaside has upon scrofulous children.

---

[1] A paper communicated to the British Congress on Tuberculosis, Section II., Medical, including Climatology and Sanatoria.

There is a second reason why a seaside sanatorium should in time be built in Holland. H.M. the Queen-Mother when she ceased to be Regent in 1898 presented her estate, Orange-Nassau, together with a sum of 250,000 francs, being part of the sum collected by the people for a national memorial in her honour, to found a sanatorium for consumptive patients. Orange-Nassau Oord lies in Gelderland, also in the east of our country, and thus will be an inland sanatorium as well. This establishment is intended for paying patients only. Her Majesty appointed a separate committee of six members to manage her sanatorium for her. It will be opened in the course of the next two or three months as well as ours, so that before the end of this year Holland will possess two large sanatoria for consumptives. A third will soon be erected by the city of Amsterdam not far from the coast of the Zuyder Zee.

As I have said, the sanatorium "Hellendoorn," which will be opened in Overysel, and so called after the neighbouring village, bears the character of other continental establishments. It will at first contain 54 beds, but it is intended to enlarge the institution to accommodate 105 patients. It is intended only for poor patients and as much as possible, that is to say, for as much as the annual contributions will allow, the inmates will be treated gratis. In order to make the number of free patients as large as possible an attempt will be made to enlarge the funds by soliciting annual contributions from the Government, the various communities, and the industrial insurance societies. The less needy patients will pay a [illegible] 3s. 6d. a day. It is arranged to [illegible] women, strictly separated from [illegible] kitchen arrangements for Jews. The principal building is in the shape of a slightly bent half-moon, opening on the south. The verandahs, where the patients will be in the open air, are in the wings, while the domestic department is on the north side, more or less by itself. The building is sheltered on the west by extensive pine woods and on the north and east by hills covered with pine woods. A beautiful view to the south and west greatly increases the attractiveness of the place. Electric light and a central heating apparatus are being laid on. The floors are covered with torgament, as is the case at Sulzhaim in Harz. It is rather expensive to put down, but its durability renders it cheaper in the end. Drinking water of excellent quality has been procured on the spot by boring. More than six patients will not be allowed in one room: generally there will only be four. Within an hour's distance there are no factory chimneys and no railways, so that there will be no fear that the air will be poisoned by either. The soil is sandy, dry, and porous. I have myself been able to prove by experiments in the sand dunes near the Hague that bacteria, among others even the rather vigorous bacillus prodigiosus, are entirely destroyed in a few days in sand, so that for a sanatorium for tuberculous patients this soil is especially suitable. As for the air itself, there are still followers to be found of the doctrine, "No cure without mountain air," but in our country we have ceased to believe this exclusively.

Last year a small private sanatorium was opened near Putten, in Gelderland, on a spot surrounded by pine woods and at about an hour's distance from the Zuyder Zee. The patients were able to be out-of-doors there until nine o'clock, or sometimes even till half-past nine, all the year round, just as well as in Honnef and other places. The results gained there will bear comparison with those gained at foreign sanatoria. The experience gathered has been short, but it does not in any way put our expectations to shame; on the contrary, it gives us reason to expect great things of a sanatorium built after the strictest and newest improvements as that at Hellendoorn will be. The patients will be subjected to a very strict *régime* analogous to the rules laid down in like foreign sanatoria. And here I venture to remark that the earnestness and perseverance with which the director and the nursing staff impress these rules upon the minds of the patients, impressing upon them their immense importance, will to a great extent fix the bounds of the useful effect of the sanatorium treatment directly and indirectly. I purposely use the word "indirectly," because, to my thinking, the indirect influence of a sanatorium is not the least of its influences.

A sanatorium for consumptives must have two useful effects: (1) the improvement of the health of the patients admitted—this is a matter of course; and (2) it must be a centre from which good and clear ideas on the subject of hygiene are constantly being spread amongst the poor and less intellectual classes. The discharged patients must be so imbued with the value of good fresh air, simple but nutritious food, a quiet, even mode of life, cleanliness of their homes as well as of their persons, and so on, that upon their return to their former life they may become the teachers of hygiene to those about them. The experience which I have had in this way, in only a few years, from different patients treated in Davos-Platz is really surprising. The patients receive a printed list of the rules which they have to keep, together with a number of useful hints which may be of benefit to them in their future life.

I cannot leave this subject without saying a few words on two points which belong to it, and which seem to me to be of the greatest importance. If the treatment in a sanatorium is to have the good and lasting effect that is to be expected, it is absolutely necessary that if the patient admitted is the bread-winner of a family (as is often the case), provision should be made for the remaining needy members of the family. The board of our society have therefore urged the sub-committees to take care that in such cases assistance is rendered to those left behind. This will relieve and cheer the mind of the patient, and have a good influence towards his or her recovery.

In the second place, care must be taken that what has been gained in the sanatorium is not lost as soon as the discharged patients return to their own unhealthy surroundings. In other words, the improvement of the houses of the working-classes should keep step with the erection of sanatoria. In dry, well-ventilated, healthy working-men's homes the entirely or partially cured patient will be able to continue in the hygienic rules of life which he began in the sanatorium, and the results gained will remain or even be improved upon. It seems to me that this is one of the most weighty points which can arise in a discussion about the benefit of sanatorium treatment. In our country various private parties are doing much in this direction. The well-known Agnetapark in Delft can be quoted as an example.

As it is especially desirable that only those patients should be admitted who are in a not [illegible] disease the application must be [illegible] with the additional advice of [illegible] man. There will be 20 of these consulting physicians appointed in different parts of the country. After their application the medical director must decide whether or not the patients can be admitted. By these means we in time hope to be able to show results which can equal any of those obtained in foreign sanatoria.

THE PROPOSED SANATORIUM FOR CONSUMPTIVES AT WINSLEY.—At the Victoria-rooms, Clifton, an influential meeting has been held in support of the proposed sanatorium for consumptives at Winsley, near Bradford-on-Avon. The Lord Mayor presided and amongst those present were the Bishop of Bristol, Dr. P. H. Pye-Smith of Guy's Hospital, Dr. Long Fox, Dr. J. A. Weatherly, Dr. Markham Skerritt, [illegible] made an appeal [illegible]

ON THE RELATIONS OF TUBERCLE BACILLI TO OTHER BACTERIA RESISTANT TO ACIDS AND TO ACTINOMYCES.[1]

BY DR. ALFRED MOELLER.

DISCOVERIES that have been made in recent years of tubercle-producing bacilli resistant to acids and similar micro-organisms have made it impossible to diagnose the tubercle bacillus by the aid of the microscope alone. Before these discoveries were made it had been customary to call every genuine bacillus that was resistant to acids and alcohol a tubercle bacillus. It is true that what was known of the similar behaviour of the lepra bacillus with respect to colour reaction already showed that the tinctorial behaviour of the tubercle bacillus was to be regarded as dependent on its other biological qualities, that in course of time it might be possible to find other bacteria which were equally resistant to acids and alcohol and with the same peculiarities with regard to colour reaction as the tubercle bacillus.

There has been a good deal of discussion as to the nature of this colour-reaction and its relation to the real substance of the bacteria. Koch himself says that from a diagnostic point of view the peculiar colour-reaction of tubercle bacilli is at any rate of value, but that it is a great mistake to think that the etiological significance of tubercle bacilli stands and falls with its specific colour reaction. Recently Klein, and later Marmorek, have shown that quite young tubercle bacilli are not resistant to acid and alcohol. Marmorek attributes this to the fact that young tubercle bacilli are not yet covered with that fatty and waxy envelope which on the one hand prevents the ordinary basic pigments from coming into contact with the protoplasm of the tubercle bacillus, and on the other hand prevents acids and alcohol from decolourising them when once stained. Klein thinks that the resistance to acids of the tubercle bacilli depends on the production of chemical substances on the part of the bodies of the bacilli. These, in the young tubercle bacilli, are wanting, and therefore they are susceptible to acids. Borrel, by experiments, succeeded in taking away the resistance to acids and alcohol of the tubercle bacilli. Under the protracted action of warm xylol a growth-like mass could be removed from the tubercle bacilli, which was resistant to acids and alcohol, whilst the tubercle bacilli thus treated had lost these qualities, though they were still capable of producing tubercle. Whatever may cause this resistance to acids in the tubercle bacillus it is quite justifiable to attribute the same tinctorial behaviour of the other bacteria, which are resistant to acids, to a like cause. But this mutual colour reaction is only the outer band that keeps the whole together; what is of much greater significance is, that there is more or less close resemblance among the bacteria, and with the tubercle bacillus, with respect to morphology and pathogenesis.

Bacteria resembling the tubercle bacillus, and known to us for years, are the lepra bacillus, smegma bacillus, and the organism of avian tuberculosis. The bacillus of leprosy was first described, in 1877, by Armauer Hansen. It was found in leprous tubercles. It resembles the tubercle bacillus in form, but is generally of more uniform length, and shorter. It stains more readily than the tubercle bacillus—*e.g.*, it stains with aqueous fuchsin solution, even at room temperature, which the tubercle bacillus will not do. Neisser, who has done much to make the bacillus of leprosy more generally known, gives Weigert's method of granule staining as the differential stain. Neither Hansen nor Neisser have succeeded in obtaining pure cultures. Bordoni-Uffreduzzi, in 1887, is alleged to have succeeded in cultivating from the marrow of the bones of a leper a micro-organism resembling the tubercle bacillus, even as regards resistance to acids. The cultures were not maintained. Cultivated bacteria from the organs of lepers, described rather later by Babes, and still more recently by Czaplewski, differ from the genuine bacillus of leprosy in their incomplete resistance to acids. Both authors maintain that the bacteria cultivated by them resemble the bacilli of diphtheria. In any case it is very doubtful whether these bacteria cultivated from leprosy are the genuine bacillus lepræ. The smegma bacillus was first discovered by Tavel and Alvarez in 1885, in the normal preputial smegma, and also in the secretion of the outer skin, particularly where a collection of epithelium may occur, as in the anal and vulvar region, in the fold of the groin, or between the toes. With respect to differential diagnosis, especially in reference to urogenital tuberculosis, the smegma bacillus is undoubtedly of greater importance.

As a micro-organism resistant to acids which has long been known, I may also mention the organism of avian tuberculosis. It differs from the organism of tuberculosis in mammals in the appearance of the cultures and the temperature conditions. Bacilli of tuberculosis of mammals will not thrive at 42° C., whilst bacilli of avian derivation will thrive at this and even higher temperatures. Fischel, who worked under Huppe's directions, says that both micro-organisms are of one and the same kind as regards nutritive media. In consequence of the different physiological nutritive media of the colder mammalian bodies on the one hand, and the warmer avian bodies on the other, a distinction has arisen between the two kinds. By artificial cultivation Fischel succeeded in bringing about approximation in outer qualities between the two bacteria: he succeeded in getting the organism of tuberculosis in mammals accustomed to a higher temperature, and in given nutritive media he got a resemblance in the appearance of the cultures, but as regards pathogenesis he could not transfer one to the other. Fischel says that he was able, with the organism of avian tuberculosis, to bring about a general tuberculosis in a guinea-pig, but the cultures derived from the organs of this animal were not identical with those of avian tuberculosis. In my own similar experiments on animals I got the same results. Tuberculosis in cold-blooded animals is in the same way to be regarded as a modification of the tuberculosis in mammals. Bataillon and Terre succeeded in cultivating tuberculosis in mammals and birds by means of passing it through the body of a frog at room temperature. Lubarsh was able to modify tuberculosis in mammals by passage through the body of a frog, so that cultures taken from the spleen of a frog grew at a temperature of as much as from 28 to30°. Dubord also cultivated cultures taken from fish inoculated with mammalian tuberculosis which also thrived at room temperature. I was able to produce cultures from the spleen of a slow-worm inoculated with sputum containing tubercle bacilli, which flourished at 20°, but which ceased to grow at a temperature of 30° and over. The cultures resembled in appearance those of avian tuberculosis. I have not yet succeeded in obtaining cultures which got accustomed again to a temperature of 37°, even after passage through warm-blooded animals.

Recently it has been possible to demonstrate a series of micro-organisms in the outer surroundings of man which in many respects resemble the tubercle bacillus. Tubercle bacilli were found in such appalling frequency in butter and milk that it led to an inquiry as to whether the genuine tubercle bacillus was really always found. Petri and Rabinowitsch were the first to make such experiments. Both succeeded in getting a bacillus resistant to acids and alcohol from butter, that was *not* the tubercle bacillus. The micro-organisms described by these two authors are so materially alike that they are both generally described as the Petri-Rabinowitsch butter bacillus.

I have lately cultivated from milk in pure culture a micro-organism similar to the tubercle bacillus which does not differ materially from the grass bacillus II. All bacteria resistant to acids cultivated from milk and its derivatives show a great resemblance to the grass bacillus. Taking into consideration the habitat of the latter—namely, cattle fodder—we are certainly justified in regarding the milk and butter bacilli as varieties of the grass bacillus. Such differences as there are—and these are very slight—may be explained by the passage through the bodies of animals. I could prove the presence of the grass bacillus in grasses much used for cattle fodder and could cultivate them in pure cultures. As they were first discovered on timothy grass (phleum pratense) I have named them timothy bacilli. The timothy bacillus has the shape of a slender little rod, sometimes slightly curved. Microscopically it is often impossible to distinguish it from the tubercle bacillus. Like the latter it often contains deeply stained granules;

---

[1] communicated to the British Congress on Tuberculosis. Pathology, including Bacteriology.

oval unstained patches are found in its interior; it divides into branches, and sometimes has club-shaped swellings at one end. In the decolourising solution, as well as in sections with the ordinary staining methods, it behaves exactly like the tubercle bacillus. The timothy bacillus grows best at incubation temperature, but it thrives badly at room temperature. It thrives on all usual nutritive media. After 36 hours, even at incubation temperature, patches of colonies are distinctly seen. The cultures generally vary considerably from those of the tubercle bacillus, but a similarity is sometimes attained if the timothy bacillus, after several passages through the bodies of animals, is cultivated at a uniform temperature of 37°. It then tends to become more like the tubercle bacillus in its slow growth. As regards pathogenesis, the timothy bacillus produces in guinea-pigs almost the same pathological changes as the Petri-Rabinowitsch butter bacillus. It has a different effect on rabbits. In them, if the timothy bacillus is injected into the veins and arteries of the animal, changes are produced which it is difficult to distinguish from true tuberculosis. There is also a variety of the grass bacillus, a micro-organism resistant to acids, found in the excreta of animals, and therefore called the "manure bacillus." I found it in a manure-heap which had lain for months, and also in the fresh excrementa of cows, donkeys, and other herbivora. The manure bacillus bears a morphological and tinctorial semblance to the timothy bacillus; in growth of cultures and in pathogenesis it also resembles the grass bacillus II.

In this *résumé* I prefer to pass over the lepra and smegma bacillus on account of their relatively rare occurrence, and because so little is known of their cultural growth, and the avian and cold-blooded mammalian tubercle bacillus on account of their unimportance as regard [illegible] fferential diagnosis. We are, therefore, left with [illegible] acilli as a primitive form, with its varieties, milk [illegible] er bacilli, and manure bacillus. With respect to [illegible] ction they all, with slight deviations, behave lik [illegible] le bacillus. The same may be said of their morpho [illegible] gh in form the different species vary more or less, [illegible] impossible microscopically, under certain condition [illegible] nguish them from the tubercle bacillus, and the t [illegible] bacillus itself varies according to the nutritive medi [illegible] t finds. I have made innumerable examinations [illegible] which I have seen the rods somewhat shorte [illegible] ger, sometimes thicker, and sometimes [illegible] kel first drew attention to the fact [illegible] in the florid form of tubercul [illegible] of short rods. Those forms wh [illegible] bacillus shape, such as rodlets, [illegible] swellings, as well as oval patches [illegible] cilli which will not stain, deeper-dye [illegible] met with in the tubercle bacillus, a [illegible] r bacteria resistant to acids. In cultural [illegible] ever, the grass bacilli differ materially from the tubercle. In the first place, in the appearance of the cultures; even when now and then a more or less close resemblance has been attained through the methods of cultivation the tuberculosis culture shows such characteristics uniformly, so that it is easy to distinguish it from all the others. Then it stands apart in its subtle behaviour with regard to temperature. Whilst other bacteria resistant to acids thrive at room temperature the tubercle bacillus requires incubation temp [illegible] The position of the tubercle bacillus is unique with r [illegible] its excessively slow [illegible] Other bacteria resistan [illegible] form visible colonies [illegible] t after 24 hours at in [illegible] temperature, wh [illegible] st moment that gro [illegible] existence of bacilli resistant to acids in the secretion of the respiratory organs, the diagnosis may be confirmed by the following simple method, based on the slow growth of the tubercle bacillus and its peculiar temperature requirements. The secretion in question is mixed with nutritive bouillon and kept at about 30°. If there is a visible increase in the bacteria resistant to acids it is certain that it is not the genuine tubercle bacillus. Sometimes in the tubercle bacillus the sputum, mixed with certain nutritive media, increases at incubation temperature. This proliferation, due in all probability to the importa [illegible] body, is, however, [illegible] after, at the latest, [illegible] bacilli a persistent further proliferation takes place at 30°. There was no pathogenic effect noticeable either in the bacteria isolated by Rabinowitsch in gangrene of the lung or in those found by me in mucus from tonsils, nose, and pharynx.

Different occurrences in practical life bring out the differentiation of pseudo-tubercle bacilli from genuine tubercle bacilli even more than at the sick-bed. I should like to give but two chief examples. For years two of our most important articles of food—milk and butter—were looked upon with lively horror because all the bacteria resistant to acids they contained were supposed to be tubercle bacilli. The isolation of manure bacillus showed the untenableness of the conclusion that the proof of bacteria resistant to acids in the excrementa of cattle was undoubtedly due to the existing bovine tuberculosis in the animals concerned. As regards pathogenesis, all bacteria resistant to acids have this in common, that they cause a tuberculous-like disease in the usual animals experimented on, the genuine tubercle bacillus always, but the pseudo-tubercle bacillus only in a limited number of cases and under certain conditions. The whole appearance of pseudo-tuberculosis in the bodies of animals bears macroscopically frequently a striking resemblance to genuine tuberculosis. But in the tubercles themselves there is a visible difference; whilst the genuine tubercles are of a solid proliferating kind, the pseudo-tubercles are of a more inflammatory character with tendency to abscess formation. The typically histological condition of genuine tuberculosis giant-cells, epithelioid cell nests, caseation, is only met with in pseudo-tuberculosis in very rare cases, when under given conditions, the bacilli are introduced into the bodies of animals. Another peculiarity of the tubercle bacillus I should still like to refer to. If, together with butter, it is injected intra-peritoneally into animals typical tuberculosis does not result, but peritonitis sets in *accompanied by severe formation of induration*, exactly the same as follows the injection of pseudo-tubercle bacilli and butter.

Though the obvious resemblances between bacteria resistant to acids and the tubercle bacillus are so many and so great, they only produce an outward relationship. As far as the real, I might say, *inner* being of the tubercle bacillus is concerned, its pathological effect on the human organism, its etiological significance in tuberculosis, it occupies a perfectly unique position among bacteria resistant to acids.

EXAMINATION OF CARCASSES IN CASES OF CATTLE TUBERCULOSIS.[1]

Illustrated by 100 Lantern Slides taken from Photographs obtained at the Carlisle Public Slaughter-house.

Hence it is incumbent upon every medical officer to make himself acquainted with at least the rudiments of cattle anatomy and pathology, and, though this may entail a heavy tax upon his time and energy, anyone who makes a practical study of the subject will be amply repaid by the novelty of the field opened out and by the light shed upon human diseases.

Those of us who have had no practical acquaintance with the post-mortem appearances of bovine tuberculosis on examining a case of so-called chronic generalised tuberculosis for the first time will doubtless be impressed with the great diversity in the naked-eye appearances of the lesions presented, many of which have a strange look to those whose pathological knowledge is confined to that of the human body. While, on the one hand, there will be no difficulty in recognising acute miliary tuberculosis of the brain and lungs, yellow tuberculous deposits in the kidney, and, perhaps, tubercle growing upon the peritoneal coats of the uterus and bladder, on the other hand, the grape-like masses—some of which are dark-purple in colour, hanging by long necks from the parietal peritoneum, the lichenous-looking masses on the surface of the liver, the great enlargement of the anterior and posterior mediastinal glands, looking like a chain of lympho-adenomatous tumours, and the enormous tuberculous solid growths, weighing many pounds, attached to the diaphragm—present characters unfamiliar to us and form in appearance a striking contrast to human tuberculous lesions.

Another striking feature of cattle tuberculosis calculated to make an impression on a novice at meat inspection is the close correspondence existing between the regional distribution of the lesions in cattle tuberculosis and human tuberculosis. Thus in cattle tuberculosis we speak of tuberculosis of the brain, the eye, the lungs and pleura, the pericardium, the bowels and peritoneum, the liver, spleen, and kidneys, and of the bladder, uterus, lymphatic glands, bones, and mamma, just as we do in the case of tuberculosis of the human body. The late Mr. Charles Darwin, in speaking of the homological structures in man and the lower animals, pointed out that man is liable to receive from the lower animals, and to communicate to them, certain well-known diseases, and that this fact proves the close similarity of their tissues and blood, both in minute structure and composition, far more plainly than does their comparison under the best microscope or by the aid of the best chemical analysis. I think that there is, perhaps, no disease common to man and animals in which this observation of Mr. Darwin is better exemplified than in the case of tuberculosis. While there is, perhaps, no tissue of the bovine body exempt from tuberculosis, that portion of the lymphatic system constituted by the lymph glands and the great lymph sacs of the thorax and abdomen are most frequently affected. A point of importance is that striped muscular tissue in the mature animal is remarkably free from tuberculosis, even when the muscle is found in close juxtaposition to tuberculous parts. This is well illustrated in the case of tubercle of either the parietal pleura or parietal peritoneum, which may be extensively involved, yet the underlying connective tissue and muscle are apparently free from tuberculous deposit.

With regard to the physical characters assumed by bovine tuberculosis in the different parts of the organism I shall not weary you with pathological details, but describe very briefly and illustrate by lantern slides the post-mortem appearances which have come under my personal observation at the Carlisle slaughter-house. The negatives for the slide-work were obtained under many difficulties and with much labour. In conducting a post-mortem examination of cattle the medical officer of health has to rely pretty much upon his own originality for the method or technique of such an examination, there being, so far as I am aware, no available book on the subject. During the course of this paper I shall refer to a few practical points on the performance of the examination which experience has suggested.

The brain.—There are two methods of exposing the brain for examination, but perhaps the most expeditious is to make a mesial antero-posterior section of the skull with a fine meat saw. Owing to the brain being fixed in its case a clean section is produced with very little disturbance of parts. The two halves of the brain are then lifted out of their respective beds for examination. I have seen at least eight cases of tuberculosis of the brain. Tubercle of the brain affords a good example of miliary tuberculosis in the ox. It generally occurs in the base, especially near the pons and medulla, but in the case from which the next slide was taken it was well marked in the walls of the lateral ventricle where numerous miliary nodules, some being collected into little heaps, were present. These little heaps or collections explain how tuberculous growths, whether great or small, are formed by the aggregation of miliary tubercles. The microscope showed the miliary nodules to be placed just below the fine epithelial lining of the ventricle, the membrane overlapping the nodule being bulged outwards. In two of the animals with brain tuberculosis oblique carriage of the head was observed, in another vertigo, and in a fourth the animal was carted into the slaughter-house in a paralysed state.

The eye.—I have several slides illustrating tuberculosis of the eye. The disease usually begins somewhere in the uveal tract, the growth pushing its way forward into the anterior chamber, where it can be seen through the cornea as a nodular growth of yellow colour. In the case from which the slides were made the tuberculous growth pretty well filled the eyeball, bulging the iris against the posterior surface of the cornea. I have never been able to find bacilli in tuberculosis of the bovine eye. The same negative result generally follows a search for tubercle bacilli in the human eye.

The pharyngeal glands.—Tuberculosis of the pharyngeal glands, especially in those of the retro-pharyngeal group, is very common and may exist with no, or only very little, evidence of tuberculosis elsewhere in the animal. So frequent is tuberculosis of the pharyngeal glands that I have been for some years in the habit of condemning the head in every case where a partial condemnation of the carcass was determined upon.

The tonsils.—The tonsils are said to be of insignificant proportions or absent in the ox. Our experience teaches us that they are always well-defined bodies opening into a cryptiform pouch, and sometimes tuberculous.

The cervical glands.—The slide shown gives a good example of tuberculosis of the upper cervical glands in a calf affected with generalised tuberculosis, including marked brain tuberculosis. It is seldom that we have an opportunity of seeing this condition of tuberculosis of the upper cervical glands owing to their being removed by the butcher when they have attained palpable dimensions. In one case we were able to get a tuberculous upper cervical gland as large as the closed fist from an animal which was apparently free from tubercle elsewhere. There is one of the lower cervical glands which from its position always escapes the vigilance of the butcher. This gland, the prescapular, is inclosed in a mass of fat in front of the anterior part of the scapula near its edge. The position of the gland corresponds to the point of the anterior border of the scapula placed opposite to the free point or acrominal end of the spine. This gland, like many other lymphatics, may be enlarged in tuberculous carcasses without displaying in its substance tuberculous deposits.

The heart.—Tuberculosis of the cardiac muscle I have never seen at the Carlisle slaughter-house, but tuberculosis of the epicardium and pericardium frequently. Nocard states that the tuberculous cuirass in tuberculous pericarditis causes atrophy of the cardiac muscles. In the cases which I have seen the heart has been much enlarged and the ventricular walls hypertrophied.

The larynx.—Several cases of tuberculosis of the interior of the larynx have come under observation at the slaughter-house. In one case there was a rounded tumour of about the size of a damson plum occupying the interior of the larynx, to which it was attached by a mobile neck at the junction of the alæ in front. The animal in which it occurred was said to have had a decided rattling sound in its throat during respiration. The tumour on microscopic examination contained numerous typical giant cells.

The lungs.—Of all the organs of the bovine body the lungs and pleura are the most frequently tuberculous, and the explanation for this I shall endeavour to offer further on. In a good many cases the disease is limited to the pleural membrane, but in the majority of cases the lungs also are involved. Tuberculous lungs are sometimes enormously increased in volume and weight from tuberculous growth. In one case a pair of lungs weighed 40 pounds, as compared with a normal weight of seven pounds. Tuberculosis of the anterior and posterior mediastinal lymph-glands forms a very remarkable feature in bovine tuberculosis. Even when the lung is little affected these glands are found to be enormously enlarged from tuberculous growth. A number of fanciful names are applied to the lesions of tuberculosis, one of which is "pommelière." The potato or apple-like form is well seen in tuberculosis of the [illegible] and not through the medium of infected air entering the bronchial tubes. In fact, we are led to believe from the post-mortem appearances that bovine tuberculosis is primarily a disease of the lymphatic system, including the great serous sacs, spreading to the various organs of the b[illegible] coverings of the organs. Therefore, when we speak of tuberculosis of the liver, spleen, uterus, and bladder, the expression often means nothing more than tuberculosis of their peritoneal coverings. If we regard the lymph-glands of the throat and neck as the chief portal of entrance of the tubercle germ it serves to explain why in cattle the pulmonary disease begins in the dorsal border of the lungs placed on each side of the vertebral column. The proneness of the apex of the human lung in the adult to tuberculosis has always afforded a subject for much theorising. A recent explanation of the frequency of apical phthisis in the adult is that of Professor Birch-Hirschfeld of Leipsic, who believes it is due to a peculiarity in the distribution of the bronchial tubes in the apex. He shows by means of fusible metal casts of the pulmonary bronchi of the human lung that the bronchi distributed to the apex pass almost at right angles from the main bronchus, thus facilitating [illegible] suspended matters of the [illegible]. A cursory glance at his [illegible], conveys the impression that suspended solid particles in the air would be just as likely to harbour in the terminal bronchi at the base of the lung. It seems probable that the proclivity of the apex to early phthisis in man is due to the direct transmission of the disease to the overlapping pleural sac through the channel of infected lymphatics in the neck.

The liver.—In the majority of cases the disease is confined to the fine peritoneal covering of the liver. The tuberculous deposits on the surface of the membrane have often a lichenous look suggestive of the appearance presented by laboratory cultures of certain micro-organisms upon artificial media, as, for example, anthrax upon sterilised potato. In the substance of the organ it occurs in the form of nodules of various sizes from a pin-head to large masses several inches in diameter, containing puruloid matter. The liver is occasionally enormously enlarged, and in one case weighed 51 pounds, the normal weight of the organ being 14 pounds.

The spleen.—In the adult animal tuberculosis of the peritoneal coat of the spleen is extremely common, but involvement of the substance with the disease is practically never seen. Congenital tuberculosis of the spleen in the calf is said to be frequently met with. It is a remarkable fact that the spleen is the only abdominal viscus in the adult animal which appears to be exempt fr[illegible] yet its peritoneal covering [illegible] tuberculous growth. Pr[illegible] singular freedom of the spleen from tuberculosis is to be found in the functional activity of the organ. Wherever we get structures freely supplied with arterial blood and where tissue change is rapid, as, for example, in the voluntary muscles and the muscle of the heart, there the bacillus *finds an* uncongenial ground for its operation. In the fœtus the spleen is inactive, and, beyond assimilating nutritive material for its growth from the fœtal blood does no physiological work. An [illegible] of the spleen from tube[illegible] curious mode of termination of the arterial capillaries which are *said* to terminate in the reticulated tissue of the pulp, thus allowing the blood to come into actual contact with the tissue elements. Arterial blood as we know is unfavourable to the existence of the bacillus tuberculosus.

The kidneys.—The kidney in the adult animal is comparatively rarely tuberculous. The early stage of the disease is manifested by yellow deposits situated, as a rule, in the peripheral portion of the cortical substance, forming conspicuous lesions when the capsule is removed. The deposits furnish good examples of tuberculous *follicles*, the fibrous formation or capsule surrounding the follicles being well marked. In one case a tuberculous tumour, firm in consistence and equal in size to a large marble, was found growing from the under surface of the renal capsule, bulging the kidney substance inwards into quite a deep depression. Tuberculosis of the kidney, according to Nocard, originates from the deep layer of the capsule or sub-capsular connective tissue. The situation of this tumour gives support to Nocard's view. I have only seen one case of tuberculosis of the bovine kidney where the disease passed beyond the stage of a few tuberculous deposits in the cortical substance. This case occurred a few months ago and was characterised by [illegible] substance where in one place a softened caseous mass existed. Suppuration of the bovine kidney would probably be as common as it is in the human subject, if circumstances were not altered in the case of the ox by the timely application of the pole-axe.

The peritoneum.—The peritoneum, like the serous sac of the pleura, exhibits the disease in the form of fine red granules, nodules, and polypoid masses. In the case of the peritoneum, however, the polypoid masses are more characteristic than they are elsewhere. Many of the polypoid growths are of a deep purple colour and their resemblance to grapes is such as to have led to tuberculosis being called the "grape disease." In Hayes's translation of Friedberger's and Fröhner's Veterinary Pathology, the grape disease is described as being synonymous with "perlsucht" or "pearl disease," but from the photographs already shown it will have been observed that there is a real pearl-like form of the tuberculous lesion as well as a grape-like form. The term "pearl disease" would be quite appropriate if applied to tuberculous growths, but gives us a very accurate conception of another and very common manifestation of thetuberculous lesion.

The uterus.—Tuberculosis of the uterine muscle and its [illegible] the lining [illegible]n. The [illegible]d, as far [illegible] than in other parts of the bovine body. The ovaries and fallopian tubes are frequently tuberculous, and in some cases the latter are enormously distended with caseous tuberculous growth, in which follicles and giant cells are abundant.

The bladder.—Bladder tuberculosis presents much the same character as tuberculosis of the uterus.

The udder.—Tuberculosis of the udder presents itself by small yellow deposits with or without calcification, cavities containing tuberculous products, or the tuberculous condition may be in the form of diffuse deposit or infiltration, which on section has a uniform yellow-white colour and cuts with a rasping feel. The naked-eye appearance of this latter form is more like cirrhosis than tuberculosis; but when a microscopical examination is made, tuberculous follicles and bacilli are found in abundance. It is important for the veterinary surgeon during his course of inspection of dairy cattle to remember the physical characters of this form, because the absence of nodulation might lead him to suppose that the induration is of a non-tuberculosis nature. In such a case the diagnosis may be helped by the tuberculin test. Induration of the udder is a common condition among dairy cattle, and we cannot expect cattle-owners to exercise much care in discriminating between a tuberculous induration and a non-tuberculous one, even if they possessed the requisite knowledge on the subject.

Bone tuberculosis.—Few opportunities are offered of seeing *bone tuberculosis in cattle carcasses owing to the circumstance* that the only sections of bone displayed are those of the spinal column and sternum. I have seen a few cases of tubercle of the sternum. The slide shows tubercle of the sternum, which probably became involved from an extension of the disease from a sub-sternal lymphatic. The tuberculous growth was easily picked out from the cancellated tissue of the bone and gave excellent examples of giant cells which were numerous and typical in character. Bone marrow is said to be an excellent culture medium for the tubercle bacillus.

The tubercle follicle may be regarded as a special arrangement and modification of the leucocyte or phagocyte for the purpose of resisting the invasion of the animal tissues by the tubercle bacillus. The giant cell forms a constant and conspicuous feature in the early stage of bovine tuberculous growth *just as it does in human tubercle. The genesis of the* so-called giant cell has always furnished material for endless discussion, the descriptions given in the various text-books as to the formation of the cell being all more or less different and equally difficult to understand. From many observations of the giant cell in bovine tubercle I think, with Metchnikoff, that its origin is capable of a more simple explanation than those usually given in which such terms as "epithelioid cells," "karyokinesis," and "karymitosis" enter very prominently. On examining a giant cell on section a central dirty-yellow granular mass is seen in which numerous tubercle bacilli are often present, as many as 50 bacilli having been counted in bird tuberculosis. Surrounding the central mass we have a row of cells which, so far as I can judge, in no way differ in character from the surrounding leucocytes of the follicle. In some cases the giant cell is composed entirely of leucocyte-looking cells, but the typical giant cell consists of a central granular mass surrounded by a row of cells arranged in the form of a circular or oval ring. What we see under the microscope is evidently only a section of the cell, and probably the original cell is in the form of a solid sphere or some modification of this form. Hence what look like young giant cells may be due to segments near the periphery or poles of the sphere. The central portion or core may be regarded as the débris of dead leucocytes engaged in conflict with the tubercle bacilli in the interior of the giant cell.

The mode of action of the leucocytes in tuberculosis is such as to suggest instinct on the part of this blood-cell. As soon as the tubercle bacilli invade the animal tissue the leucocytes or phagocytes squeeze their plastic bodies through the walls of the neighbouring capillaries and go for the bacilli, which they isolate in groups and surround, forming the so-called giant cells. Many of the leucocytes of the giant cells are killed in their action against the bacilli, the débris of their bodies constituting the yellow material in the centre of the tubercle follicle. Outside the active zone of giant cells there is a zone of phagocyte reserves, and beyond this a zone of outposts engaged in constructing a fibrous wall to prevent further advance of the enemy.

TUBERCULIN AS A DIAGNOSTIC AGENT.[1]

BY HAROLD SESSIONS, F.R.C.V.S., F.H.A.S.

IN the present state of our knowledge it must be allowed that tuberculosis is a disease of a contagious nature—a virulent death-dealing disease that can pass from one animal to another and from one species to another. The power of resistance to the disease varies in different species of animals and even in different families or individuals of the same species. Allowing for these variations the fact remains that we have this death-dealing disease, terrible in its ravages, and we are met here to-day to ask ourselves and each other what means are the most effectual that we can direct towards lessening these ravages? The total eradication of the disease we may safely leave to the care of some future conference.

Apart from human beings, the animal in which tuberculosis chiefly shows itself is the cow. The two are so intimately connected in civilised life that it is natural that a good deal of danger is apprehended that the disease may pass either through the milk or flesh of an affected cow to a human being, or from a tuberculous human being to a cow. But quite apart from any danger to human beings, I have long held and advanced the view that the ravages of tuberculosis among our domestic animals is so great that for that cause alone we are fully warranted in taking all needful measures for its curtailment now, because we can get rid of it in the domestic animals long before we can do so among human beings.

After the first recognition of the disease some years ago the trouble that we had to contend with was to get an approximately correct diagnosis, and I think I may say, without fear of contradiction, that, except in advanced cases, we could not with any certainty diagnose 5 per cent. of affected animals. With the discovery of tuberculin a fresh stage was marked in the diagnosis of the disease. We soon found that we had an agent which had a marked effect on animals affected with the disease, and the next few years were devoted to brilliant anticipation, study, and rash assertions of the power of tuberculin. I wish to take this opportunity to remind and to emphasise the fact to some of the critics of the power of tuberculin that during those years many of us worked, not, as some people seem to think, to find out cases in favour of tuberculin, but to find out whether we could obtain any reliable results from its use and what those results were likely to be. Using some of the first tuberculin obtainable on cattle of my own the results appeared to be far from satisfactory. It was only after a prolonged and careful working under a variety of conditions that I became an advocate for its use.

I do not propose to deal with tuberculin from a laboratory point of view, because there are others better able to do so than I, and having been on the Army Remount Commissions during the last 12 months in Spain and South America I have not had the facilities needful to keep in touch with the advance recently made. I have been able to see and to hear a good deal as to the value of tuberculin from a practical and commercial point of view. The proposition which I put forward is, concisely, "It is expedient to use tuberculin for diagnostic purposes in cattle." At one time there appeared in the press a number of loose statements as to the incorrect results given, and the contradictory results obtained by using tuberculin. Some of the statements I took the trouble to follow up and invariably found that they were neither exact nor correct. They may have arisen:—(1) From a tuberculin being used that was old or inefficacious; (2) from the test being hurriedly or improperly performed; (3) from errors at the post-mortem examination; and (4) from the inability of the operator to understand what he sees.

1. *Old or inefficient tuberculin.*—Some few years ago I suggested that tuberculin was much too dangerous an article to be sold, except under strict supervision, and that the whole community would benefit by such supervision. A central authority alone should issue tuberculin; and though they might and probably would license several competent people to make it, all that is made should pass through their hands for issue. They should demand that with all tuberculin sent out within a month a report of how and where it was used should be sent to them, and as far as possible the results obtained with official temperature charts filled up. This would lessen the risk of the indiscriminate use of tuberculin and the chance of one animal being re-tested within a week or so. It would also form a basis for much-needed statistics. I consider this a most important point and shall bring forward a motion to that effect later.

2. *Hurried or improper performance of the test.*—Few people seem to realise how very delicate a physiological reaction the test is; and that only when an animal is in a perfectly normal condition can the test be applied. That in the case of cattle even bringing them in from a field to tie them up in a shed when they are not regularly tied up is enough to upset them for two or three days to such an extent that you may not be able to test them. It is quite natural that those who have animals which they want tested should desire to have them tested as quickly, cheaply, and with as little trouble as possible; and those who test animals have continually to fight against these influences. Otherwise the test results being incorrect they will bring on the tuberculin test a discredit that is not properly its own.

3. *Errors at the post-mortem examination.*—To make a post-mortem examination requires much time and skill, and simply cutting open an animal and looking at the larger organs cannot be regarded as a post-mortem examination. When after a reaction of tuberculin an animal is killed and no visible lesions are found, before believing that the test is wrong I always ask myself whether the post-mortem report is not quite as likely to be incorrect. I would even go a step further. It seems to me that a tuberculin reaction may be obtained when an animal is in the very early stages of tuberculosis and before there are definite marked lesions in the tissues. I should consider this to be very probably the case when animals from an inspected herd react to the tuberculin test and on slaughter show no post-mortem symptoms of the disease. If animals bred on a farm on which tuberculosis does not exist, and as far as can be ascertained there is no probability of the animals being affected, a reaction with negative post-mortem results may well be viewed as due to the tuberculin test if the conditions under which the test was applied were accurate—it may reasonably be called an error.

4. *Inability of the operator to interpret the facts.*—Several times I have met with cases where, after an animal had been

---

[1] A paper communicated to the British Congress on Tuberculosis. Section IV., Veterinary.

tested and a typical tuberculosis reaction had been obtained animals have been declared free from disease. On the other hand, cases have occurred where an animal's temperature has risen suddenly during the test, not in a typical manner, and no allowance has been made for an extraneous cause. A system of sending all temperature charts to a central authority and having them reduced to a graphic form would very materially help to eliminate this class of mistake. There is not time in this paper to advance the evidence in favour of correct results obtained by the use of tuberculin; I have already done that in some detail in a small book that, conjointly with Dr. T. M. Legge, I wrote after the publication of the report of the last Parliamentary Commission. I will therefore sum up the evidence in a sentence by saying that there are many thousand instances recorded where tuberculin has given correct results and these in cases where there were no other means of diagnosis. On the other hand, there are advanced some instances—not a very great number—where apparently the tuberculin test has been wrong. Amongst these, some of the cases that have been most prominently brought before the public are those of animals sold in Europe as being free from tuberculosis, but which two or three months afterwards have been tested in the Argentine and found diseased.

I had the opportunity while in the Argentine of talking over this matter both with the Minister of Agriculture, Dr. Garcia Merou, and wit [illegible] and also I saw [illegible] a necropsy. I [illegible] culture with a very carefully worked-out series of answers to some questions which I raised as to the progress of the disease in the Argentine and what he considered the best means of checking it. He further kindly supplied me with copies of charts of temperatures of animals tested, post-mortem results, and in some cases with the certificates that had come from Europe. Between the dates of April 12th, 1898, and Nov. 15th, 1900, 2092 imported animals were tested, out of which 158 animals reacted to the tuberculin test. Of these 158 animals 51 were slaughtered and 107 were re-shipped principally to the Republic of Uruguay. They were re-shipped, because since April, 1898, no animal is allowed to enter the Argentine until it has been tested by tuberculin under the authority of the Argentine Government and certified as free from tuberculosis. If the animal reacts it has, if left in the docks, *to be slaughtered.* However, in January, 1900, the Government of Uruguay also established an import sanitary inspection; and as since that date no rejected animals have been re-exported there and only a few are re-exported to Chili and Brazil, almost all those that show any reaction are now slaughtered at the Argentine sanitary stations. Of the 51 animals that were slaughtered 50 proved on post-mortem examination to be diseased, the macroscopical diagnosis being confirmed by microscopical observations and inoculations on guinea-pigs. The one case that was incorrect was that of a bull that had swallowed a four-inch nail, which, perforating the stomach, had formed an abscess, causing septic infection with a rise of temperature. The rise of temperature was not typical and it was suggested by the veterinary inspector that the animal should be considered doubtful and re-tested, but it was thought, as it was a suspicious case, that it would be wiser to have it killed. These 2092 animals were nearly all pedigree cattle of value, some selling for several hundreds of pounds. At least 1750 had been tested in Europe before embarkation, and of these a total of over 1600 tests agreed in Europe and the Argentine. There were, on the other hand, over a hundred discrepancies. Can these be satisfactorily accounted for? I feel convinced from what I have seen and the information in my possession that the error in very many of the cases was made in Europe. The animals were tested sometimes in remote country places—sometimes after a railway journey; and doubtless in not a few instances the *animal* to be exported was the first one that had been tested by the operator, and experience had not taught him the need for great care. Again, it is possible under the present system of free use of tuberculin that a veterinary surgeon may test an animal and finding it to react the owner may at once sell it, and within a week another veterinary surgeon may test the animal for exportation, being quite unaware of the first test. The result and the certificate on which the animal is exported are wrong, because it is well known that you cannot correctly test an animal within some weeks of an injection of tuberculin. Again, it is quite conceivable that an owner may test an animal on his own account—there is nothing to prevent it—and then, not being satisfied with his own work, call within a few days for an expert opinion without admitting the fact that he has already tested the animal. All these and many other circumstances have to be considered by the practical mind before accepting all these discrepancies as being due to the tuberculin.

There is another point, too, that has to be considered. Between the two tests animals pass through the tropics, and in one or two cases I found while analysing these figures that an animal certified healthy in England had been carried by the same boat, and probably in the same stall, as an animal which the previous voyage had been slaughtered on landing and found diseased. This second animal on arriving at the Argentine reacted to tuberculin and a post-mortem examination showed it to be diseased. In view of the very contagious nature of the disease among show animals new fittings, mangers, &c., should always be used when conveying valuable animals. Besides these 2092 imported animals the tuberculin test has been officially applied in the Argentine to 52,716 dairy cattle and 21,873 other cattle, and the test is believed to be of practical value.

In passing, it may be interesting to observe that in the province of Buenos Ayres the percentage of animals affected with tuberculosis, as revealed in the slaughter-houses, is 0·476 per cent. on the total of 1899. The percentage increases to 2·32 in the highly-crossed Shorthorn cattle killed and decreases to 0·0012 in pure native cattle. Consequently it may be inferred that the number of animals affected increases in proportion to the higher degree of crossing with improved imported stock. During the last five years in the Argentine the slaughter-house returns show an increase of tuberculosis. In 1895 the percentage on the total number of animals slaughtered was 0·281; in 1896, it was 0·467. Considering these figures and the very strong feeling that the Argentine Government appear to have as to the need of testing all animals before they are allowed to enter the country, I raised the question as to whether when the re-embarkation of pedigree stock commenced, a *modus vivendi* could not be arrived at to prevent animals after having reached the Argentine being thrown on the importers' hands, causing much expense and friction. I am glad to say from the information supplied me that that Government would be quite willing to make suitable arrangements *to test animals in England before embarkation, provided* our Board of Agriculture would on their part furnish guarantee as to the testing, which they might very well do.

[illegible] in [illegible] En [illegible] at the same time, the statistics which I have quoted show the danger of an increase of tuberculosis in their large and valuable herds; and they are right in doing all they can to check its further inroads. For the good of their country, if tuberculin was correct in only 80 per cent. of cases, it must be of manifest advantage to use it; whereas, from our present information, it can be correct in over 95 per cent. of cases where it is used.

I have no doubt that many of the points which I have touched upon will lend themselves to your criticism, and that in the press afterwards, perhaps more than at this meeting, instances will be adduced to show that tuberculin is not reliable, but, in anticipating them, may I venture to reply that I have been careful in this paper to make the claims of tuberculin moderate, and that I have before writing considered and thought over from a practical and scientific aspect the objections already published, and I believe that under proper control tuberculin is a safe and reliable agent to use and the only means we have at present for approximately diagnosing tuberculosis in cattle.

In conclusion, I would beg to move that this Congress, believing that tuberculin is an efficacious and reliable diagnostic agent, liable to gross misuse whereby it becomes a public danger, would ask the Minister of Agriculture and the President of the Board of Trade whether it would not be feasible to allow tuberculin to be issued by a central authority only, who should demand from those who use it a statement of the results obtained. The advantages derived being the use of properly prepared standard tuberculin, the compilation of much-needed statistics, the minimising of the danger of the fraudulent or wrong use of tuberculin, and the supervision of the temperature charts.

> Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus Morb.*, lib. iv., Proœmium.

BRADFORD ROYAL INFIRMARY.

A CASE OF MALIGNANT INTUSSUSCEPTION OF THE SIGMOID FLEXURE; REMOVAL BY THE RECTAL ROUTE; RECOVERY.

(Under the care of Mr. J. BASIL HALL.)

THE junction of the sigmoid flexure and the rectum is frequently the site of a malignant growth, yet this seldom *gives rise to an intussusception.* Should, however, an invagination occur and the tumour present at the anus, the growth may be removed per anum and the intussusception relieved at the same time, though the cases in which this is advisable are not numerous, for usually a laparotomy would make resection of the bowel easier with a very slight increase in the risk.

A man, aged 56 years, was admitted into the Bradford Royal Infirmary on Oct. 14th, 1900, with all the signs of acute supervening upon chronic intestinal obstruction. He stated that 12 days prior to admission, without any previous symptoms, rectal tenesmus commenced, followed by the frequent passage of loose motions containing much blood and mucus. Vomiting soon set in, the abdomen became distended, and his condition passed into one of acute obstruction. On admission the patient looked much older than his years; his abdomen was considerably distended but still moved with respiration. The tongue was moist but very dirty and the breath was most offensive. The pulse was quick, soft, and compressible; the temperature was 99·8° F. The hands and feet were cold and his condition generally was feeble. On rectal examination the finger impinged one and a half inches from the anus *upon an intussusception* with an annular carcinoma at the apex. The mass appeared to be about five inches long. There was much sanious and offensive discharge.

Under ether, after stretching the sphincter, a view of the mass was obtained. It was quite black, with every appearance of sloughing. It was therefore decided, considering the condition of the patient, to relieve the obstruction by opening the colon in the iliac region and at the same time *to gain what information could be obtained through the* colotomy wound. The obstruction was thus temporarily relieved, but contrary to expectations no sloughing of the mass occurred except a superficial necrosis at its apex. At the end of 10 days therefore Mr. Hall decided to attempt resection after Mr. A. E. Barker's method. Ether being given the anus was divided posteriorly and the coccyx was excised, thus exposing about half the mass. A stout silk cord was then *slipped over it and the intussusception was dragged* as low as possible. Three silk ligatures were then passed with a hernia needle as near the base as possible. Each ligature included about one-third of the circumference of the wall of the intussuscipiens and the intussusceptum together, and the mass was then amputated below them. A stump about one inch long was left which it was calculated would speedily be obliterated on account of the great traction upon it. The opening in the rectum was closed. The silk ligatures were left long and hanging through the anus.

After the operation the patient recovered fairly rapidly but the silk ligatures did not come away, becoming loose without cutting through the segment of bowel included within them. At first this was attributed to the stump becoming less swollen and œdematous. Three weeks later, *however, a prolapse of the remaining three* inches of the sigmoid occurred through the colotomy wound. This piece of gut had a blind end and it then became evident that owing to the great traction it had been drawn up as soon as the ligatures had cut through and its lower extremity had then closed. On examination again under ether it was found that the distance between the remaining portions of sigmoid and rectum was so great as to exclude any possibility of uniting them. The remaining portion of the sigmoid was accordingly excised through the colotomy wound. The condition of the patient, therefore, was as follows. The descending colon ended by an artificial anus in the left iliac region; below this point the whole of the bowel had been removed with the exception of a small portion of rectum which ended blindly about five inches above the anus. The general health was excellent. The patient wore a well-fitting belt of webbing in which was a cup (similar to that on the colotomy truss) which covered the colotomy opening. This arrangement suited him better than a truss, as it allowed him to stoop and to undertake manual labour without chafing or becoming displaced.

The intussusception removed measured four inches. This, together with the inch left at the operation, represented about 10 inches of bowel. The base of the intussusception, therefore, was about six and a half inches and the growth was 11½ inches from the anus. Microscopically, the growth was of the usual columnar type.

Remarks by Mr. HALL.—It is now 13 years since Mr Barker[1] published the first case in which he successfully resected a malignant intussusception per anum, and the rarity of such an opportunity is shown by the very few records of this procedure. Indeed, with the exception of the examples in Mr. Barker's first publication and his second case recorded five years later,[2] I am not aware of any other published cases. In the case recorded above the operation cannot strictly be said to have been performed "per anum," since the sphincter had to be divided and the coccyx excised before the base of the intussusception could be reached, but the case bears sufficient resemblance to those of Mr. Barker to be classed with them.

One of the most interesting points in the case was the manner in which the small remnant of sigmoid flexure protruded through the colotomy opening. I have spoken of it as a prolapse, but, strictly speaking, the protrusion always commenced as a true *retrograde intussusception* which became a complete prolapse as soon as the whole length of gut had escaped. In consequence of the shortness of this remnant portion of bowel the intussusception stage of the protrusion was necessarily of brief duration, but on more than one occasion I satisfied myself that a true retrograde intussusception occurred. This phenomenon has been observed before under similar conditions and recorded by Lawford Knaggs,[3] Golding-Bird,[4] and Barth[5] *It is not necessarily* associated with the existence of an obstruction below the artificial anus, for in Golding-Bird's case a retrograde intussusception occurred through a patent Meckel's diverticulum It is apparently a reflex phenomenon produced by the surface irritation from the artificial anus. In the present case the protrusion not infrequently occurred when the dressings were removed and the abdomen was exposed to the cold air—a fact which lends colour to the view that *occasionally* intussusception is the result of irregular peristalsis set up by reflex nervous impulses.

BRITISH GYNÆCOLOGICAL SOCIETY.

Complications and Degenerations of Fibroid Tumours of the Uterus as bearing upon the Treatment of these Growths

A MEETING of this society was held on July 11th, Dr J. A. MANSELL MOULLIN, the President, being in the chair

Dr. CHARLES NOBLE (Philadelphia) read a paper on the Complications and Degenerations of Fibroid Tumours of the Uterus as bearing upon the Treatment of these Growths Hæmorrhage was by no means their chief and only danger; there were the risks of necrosis, of myxomatous or cystic degeneration, of calcareous infiltration, of associated malignant disease, and of complicating adnexal affections, and even their indirect effects upon the alimentary, vascular, and nervous systems might lead to death or invalidism. Dr. Noble then gave details in tabulated form of 218 cases of fibromyoma uteri upon which he had operated up to May 24th, 1901. Had operation not been performed the complications which were found to be present in 66 of these must inevitably have proved fatal, in 25 others they would have imperilled life, and they would have rendered 30 of the remaining patients chronic invalids. Therefore 78 of these 218 patients would, at a low estimate, have died from the complications present, while 15 would probably have been the lowest death-roll from hæmorrhage, chronic anæmia, car[illegible] other direct effects of th[illegible] mated total mortality of [illegible] malignant disease and large ovarian tumours were not included, at least a third of the patients would have died as a result of the tumour or of its complications. The disappearance of fibroid tumours after the menopause or after pregnancy was merely one of the curiosities in the history of these growths. In women with fibroids the menopause was delayed for from three to 10 years and even if improvement followed it necrosis of the tumour might subsequently take place. Twelve of his patients were over 50 years of age when they sought relief from sufferings which, according to classical teaching, should have already ceased. Only 91 of his patients had been pregnant. Deaths directly due to fibroid tumours were seldom recorded, as when the symptoms became grave operation was generally resorted to. Those advocating the expectant treatment agreed that when hæmorrhages had produced profound anæmia operation was indicated; yet anæmia materially increased the risk of narcosis, œdema of the lung, and sepsis, and anæmia when established might prove very intractable. Adhesions had in many cases increased the difficulty and risk of operation, while phlebitis and embolism had proved a source of danger both before and after it. In short, if left alone, more than one-third of his own cases would have ended fatally, in more than one-fourth the patients would have been chronic invalids, and of the remaining one-third but few would not have been incommoded by the presence of the tumour. It was difficult to say whether his own was or was not an average experience. The only table of cases resembling that upon which he based his observations was published by A. Martin, who had tabulated 205 cases, analysing the complications met with. Martin, however, made no reference to the condition of the adnexa. Allowing for this difference in [illegible] similar. At [illegible] the result of [illegible] he mortality [illegible] uly operation not only reduced the mortality from the disease from over 33·3 to less than 10 per cent., but saved the patient a long period of invalidism otherwise unavoidable. Small multinodular sub-peritoneal fibroids in women over 40 years of age were those least likely to grow or to cause serious trouble, and there was a small percentage of cases in which operation was not more advisable than was expectancy.

[5] Deutsche Zeitschrift für Chirurgie, vol. xxvi.

The PRESIDENT, in drawing attention to a collection of specimens exhibited in reference to Dr. Noble's paper and which had been brought together by Dr. Macnaughton Jones, said that he thought that he was correct in saying that such a collection had never before been on one table. The specimens incl[illegible] cystic, mucoid[illegible] others which [illegible] rhage had tak[illegible] several in which, in addition to the myoma, a carcinomatous, sarcomatous, or cysto-sarcomatous tumour was present; a single, large, semi-fluctuating fibroma (exhibited by Dr. Snow and termed by him "monoma") which showed in one portion isolated tissue resembling carcinoma, a microscopical slide in this [illegible] the museum preparation; [illegible] ldition to the myoma uteri, [illegible] f the adnexa and broad ligaments.

Dr. H. MACNAUGHTON JONES, in opening the discussion, said that an examination which he had made of the specimens preserved in the museum of the Royal College of Surgeons of England and in the museums of several of the larger London hospitals showed that 85 per cent. of the tumours had undergone degeneration or were accompanied by some serious complication. It also rendered very evident the fact that a vast mass of material, invaluable in estimating the dangers and consequences of these growths, had passed through these hospitals and had been lost. Countless tumours had also been shown at societies of which no microscopical or even careful examination had been made, though the time had passed when it was of advantage to demonstrate the feasibility of their removal. One danger not often realised was that other pathological conditions of the uterus and adnexa were, by excusable errors of diagnosis, liable to be mistaken for fibromata and, even though of a fatal nature, allowed to remain without surgical relief until their removal had become difficult or impossible. Considering the frequency with which various degenerations and complications of these tumours were now known to occur he warmly advocated surgical treatment of them.

Mr. F. BOWREMAN JESSETT did not agree with Dr. Noble as to the relative frequency with which carcinoma and sarcoma co-existed with fibromata. He could remember at least five cases in his own practice in which the pathologist pronounced a portion of a fibroid tumour to be of a sarcomatous nature. The position of the tumour should be considered when determining the treatment; if subperitoneal it might in a large number of cases be permitted to remain. When submucous or interstitial myomata gave rise to hæmorrhage or symptoms of pressure, or were necrotic or of rapid growth, they should be removed. The opposite conditions prevailing, the surgeon could afford to wait.

Mrs. SCHARLIEB believed that a certain number of fibromata decreased in size after the menopause, yet waiting for any very problematical benefits which might then ensue involved serious risk. The youngest patient on whom Dr. Noble had operated was 17 years of age. She had removed, with Mrs. Stanley Boyd, a tumour from the anterior wall of the uterus of a girl 15 years of age. The edges of the uterine incision had been brought together and the uterus and its appendages had been left complete.

Mrs. STANLEY BOYD referred to the difficulty of distinguishing between a tumour which had been sarcomatous *ab initio* and one found on removal to be sarcomatous but which had become so as the result of degeneration in a fibroma. She asked Dr. Noble whether in his experience curetting ever permanently arrested hæmorrhage produced by a fibroid tumour. She regarded it as a temporary measure to arrest hæmorrhage, possibly with a view of encouraging the patient to undergo the major operation at a later date.

Dr. HERBERT SNOW said that the soft œdematous solitary fibroid first differentiated by Mr. Lawson Tait had from its inception a malignant tendency peculiar to itself. The common multiple, hard fibroid in a few rare instances underwent cysto-sarcomatous degeneration. Carcinoma might be present as a coincidental complication or as a result of the irritation and vascularity produced by a fibroma.

Mr. STANLEY BOYD said that the etiology of certain complications was obvious, as, for example, necrotic or other change in the tumour itself, salpingitis or pyelitis, but such a condition as cancer must be necessarily accidental, being a growth of epiblastic tissue. Sarcomatous degeneration was theoretically conceivable. A mesoblastic tissue already growing abnormally might apparently easily take on a sarcomatous nature. True degeneration, however, he believed to be rare.

Dr. HEYWOOD SMITH took exception to the statement that parturition was not followed by a shrinkage in the tumour.

Dr. J. MACPHERSON LAWRIE agreed with Mr. Bowreman Jessett rather than with the reader of the paper as to the indications for and against operation.

Dr. SKENE KEITH was much opposed to operation to the extent which had generally been approved.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION.

Exhibition of Cases and Specimens.—Tumours of the Pharynx from their Clinical Aspect.

A GENERAL meeting of this association was held on July 12th, Mr. MAYO COLLIER, the President, being in the chair.

The PRESIDENT showed a case of Double Optic Neuritis with Paralysis of both External Recti following Right Tympanic Disease. The interesting point was the cause of the neuritis.—Dr. C. O. HAWTHORNE suggested cavernous sinus thrombosis.—Dr. DUNDAS GRANT spoke of the possibility of tubercle.—Dr. R. H. WOODS also spoke.—The PRESIDENT, in his reply, objected on anatomical grounds to implication of the cavernous sinus.

The PRESIDENT also related a case of Deafness due to Chronic Sclerosis of the Middle Ear which had been greatly improved after relief of nasal obstruction, and he showed a case of Epithelioma of the Maxillary Antrum nine months after operation, in which there had been, so far, no return.

Dr. BARCLAY BARON showed a case of Complete Aphonia with Close Approximation of the Cords. It had resisted all treatment, and was brought forward for diagnosis and suggestions for treatment.—There was general agreement that the case was functional, chloroform narcosis, hypnotism, and the cautery to the enlarged veins at the base of the tongue being variously proposed.

Mr. LENNOX BROWNE showed a specimen of a Fibro-Myxomatous Polypus, removed from behind the Palate, which was found to have proceeded from the maxillary antrum through the opening in the inferior meatus made during the course of operation performed some months previously for the relief of maxillary empyema.

Mr. LENNOX BROWNE also showed the following: 1. A case of Pretuberculous Condition of the Larynx in a patient who had been treated by him 20 years previously for traumatic perichondritis due to the impaction of a chicken-bone in the larynx. The patient had since developed symptoms which pointed to tubercle, but both pulmonary and laryngeal evidences had been, to say the least, inconclusive. The main feature was recurrent aphasia, but with phonetic cough. 2. A patient with Sarcoma of the Pharynx who had been exhibited twice previously—first in March before removal, secondly in May after removal—and now again, to demonstrate, first, that a certain amount of infiltration suggestive of a possible recurrence had entirely subsided, and, secondly, in regard to the epiglottis which, formerly compressed by the growth, had now entirely recovered its form and position. 3. A patient, aged 66 years, with an Enormous Tonsil and Glandular Infiltration which had existed for three months, and which up to now, though causing comparatively little difficulty in swallowing, had been the occasion of severe pain. The microscopical examination revealed that the growth was a sarcoma, and it was suggested that although quite inoperable the case was one suitable for treatment by Coley's fluid, of which the exhibitor had had more than one favourable experience.—The PRESIDENT, commenting on the interest of the third case, expressed the opinion that the majority of malignant tumours of the tonsil were sarcomata.

Dr. A. McCOLL showed a patient suffering from Laryngeal Tuberculosis in an advanced stage which had been treated by insufflations of resorcin and orthoform. Both deglutition and voice had been greatly improved and the laryngoscope showed several cicatrices of healing. The general treatment had been that of "open air" and the patient had gained a stone in weight.—The PRESIDENT, Mr. LENNOX BROWNE, and Dr. DUNDAS GRANT spoke in congratulatory terms on the result.

Dr. S. LODGE showed a patient with Lupus of the Nose cured by Excision according to the method of Anderson with an artificial nose of aluminium made by the patient himself which had proved a greater success than one of ordinary manufacture.

Dr. DUNDAS GRANT showed: (1) a case of Post-Diphtherial Paralysis; (2) a case of Ulceration of the Tongue, probably malignant; and (3) a case of Thrombosis of the Jugular Vein.

Dr. WOODS opened a special discussion on Tumours of the Pharynx from their Clinical Aspect. He related several cases in his own practice both in the naso-pharynx and in the lower pharynx and his methods of operating. The chief interest turned on the advisability of operation.—Mr. LENNOX BROWNE spoke in favour of removal at the earliest possible moment after diagnosis and related several cases.—The PRESIDENT discussed the question from the point of view of surgical anatomy, giving several fatal instances which, from the experience of others, might have been successful had they been attacked with courage in their early history.—Dr. DUNDAS GRANT confessed himself at a loss to account for the undoubted hesitancy of even bold surgeons to interfere with these cases, considering the great advances that had been made in radical operations generally.—Dr. LODGE related a case of, and showed photographs of a successful operation for, Removal of a Sarcoma of the Naso-pharynx and of Involved Cervical Glands.

Reviews and Notices of Books.

Einführung in die Augenheilkunde. Von Dr. J. HIRSCHBERG, Ord. Honorar-Professor an der Universität zu Berlin, Geh. Med.-Rath. Zweite Hälfte, erste Abtheilung. Mit 113 Figuren und einen Titelbild. (*Introduction to the Study of Diseases of the Eye.* By Dr. J. HIRSCHBERG. Second half, first division. With 113 Figures and a Chromograph.) Leipsic: George Thieme. 1901. 8vo. Pp. 249. Price 9 marks.

THIS part of Dr. Hirschberg's manual maintains the high reputation of its author. It is a matter for regret that his numerous engagements should have left him so little time for scientific work that nine years have elapsed since the appearance of the first part published in 1893. The students who read and profited by the perusal of that first part must have begun long ago to practise for themselves and will hardly require to be taught the principles required to be known and understood for the successful treatment of refraction cases. Dr. Hirschberg commences this portion of his work with the subject of Ophthalmoscopy, describing the invention of the ophthalmoscope by Helmholtz and its gradual improvement by Rekoss, Helmholtz's assistant, and others. He relates with some humour an event that happened to himself as he crossed the Atlantic "Do you know," he was asked by an American, "my nephew who invented the ophthalmoscope?" "Certainly I do," replied Dr. Hirschberg, "and in Europe we call him Helmholtz." "The ophthalmoscope appears to be a French discovery," says another, a Frenchman, and we think we have heard the name of Cummings cited as the real originator of it by—an Englishman. It has certainly proved an invaluable aid in the recognition and diagnosis of the diseases of the eye, and upwards of a hundred modifications have been suggested, with all of which, says the learned professor, the practised observer can see the fundus of the eye and of many of which he describes the construction. He discusses the character of the illuminant that is used, and very properly objects to sunlight except under certain special conditions. He seems to prefer an oil lamp. In England it is probable that an Argand gas burner is most commonly in use. In regard to the red colour of the fundus as seen through the ophthalmoscope it is attributable, he says, to the light emerging from the observed eye being tinted in part by the retinal pigment and the pigment of the choroid, but mainly by the vessels of the choroid which absorb the blue and the violet rays. It is certainly not exclusively caused by the "visual red" as was in the first instance erroneously supposed by its discoverer Boll. Dr. Hirschberg describes at considerable length and with great clearness the respective motions of corneal, lenticular, and vitreous opacities under different positions of the observer, both with and without the employment of lenses. A long and interesting chapter is devoted to the pathologically formed precorneal plexuses of vessels. A historical summary is given of the observations that have been made on these vessels from the date of the Arabian physician El-Razi in the tenth century to the present time. Dr. Hirschberg's own researches agree with those of Professor Schöbl whose beautiful injections show that two sets of vascular loops are normally present—a coarser set continuous with the conjunctival and episcleral vessels and a finer set continuous with the scleral vessels. The extension and development over the corneal surface of the former set result in the pannus crassus that is seen in cases of granular lids, whilst the deeper-lying set give origin to the vessels present in interstitial keratitis and forming the salmon-coloured patches of Hutchinson in syphilitic inflammations. In pannus crassus the vessels form plexuses of tree-like aspect, whilst in pannus tenuis their distribution resembles a brush. Once formed they are permanent and may be seen by transmitted light with a strong lens behind the ophthalmoscope, as Dr. Hirschberg believes he was the first to demonstrate. Under the general heading of Ophthalmoscopy Dr. Hirschberg gives, logically enough, an account of the opacities of the lens and in the vitreous—including, therefore, the different forms of cataract—the recognition of foreign bodies and cholesterine crystals in the eye, and, finally, the objective diagnosis of errors of refraction. This branch of ophthalmology is treated very skilfully and at great length, the physical and mathematical side of the subject being particularly dwelt upon. The remaining section of the work, dealing with the symptomatology and treatment of diseases of the eye and with the operative procedures, will, we trust, appear at an early date.

Dental Surgery, including Surgical Anatomy and Pathology: a Manual for Students and Practitioners. By HENRY SEWILL, M.R.C.S. Eng., L.D.S.R.C.S. Eng. Fourth edition, edited by W. J. ENGLAND, L.D.S.R.C.S. Eng., and J. SEFTON SEWILL, M.R.C.S. Eng., L.R.C.P. Lond., L.D.S.R.C.S. Eng. London: Baillière, Tindall, and Cox. 1901. Pp. 622. Price 10*s.* 6*d.* net.

THE present edition of this book is an advance on previous ones. The subject-matter has been considerably increased, new illustrations have been added, and the work all through has been subjected to revision. There is, however, room for further improvement, and in its present form the work cannot be regarded as a thoroughly trustworthy text-book for the student. Many subjects are scantily treated, many points on which stress should be laid in teaching are omitted, and some of the principles laid down are liable to misinterpretation by the student.

The first three chapters are devoted to (1) the Anatomy and Histology of the Teeth; (2) the Development of the Teeth; and (3) the Growth of the Jaws. To the text are added some excellent illustrations, most of which are from photo-micrographs and sections by Mr. Charters White, Mr. Arthur Underwood, and Mr Hopewell Smith. These chapters are the most attractive in the book.

In the section dealing with irregularities in position of the teeth there is much to be desired—the classification is far from being clear; indeed, for the purpose of teaching it is almost useless. The etiology is scanty and the treatment in many places is not in keeping with present-day ideas. There is a decided leaning nowadays, and justly so, to treating irregularities at their early stage by the judicious extraction of teeth, and in many cases of the unerupted premolars. This latter line of treatment has been shown to produce excellent results, especially in that difficult type of irregularity known as superior protrusion. Early treatment, however, does not seem to be approved of by the editors of this book, and the reason is given on page 128—viz., that the operation is somewhat severe and necessitates a rather prolonged anæsthesia, making it, according to them, necessary to administer ether or chloroform, the prolonged method of administering nitrous oxide being apparently lost sight of. To their contention that the cases in which the early treatment is recommended can be remedied by ordinary methods we would point out that the great advantage of early treatment is that a crowded condition of the teeth is avoided and therefore mechanical treatment is unnecessary.

There is an excellent description of caries, with a good number of illustrations. In the section dealing with the artificial production of caries reference is made to the work of Mr. Pound and Mr. Sewill, but hardly sufficient credit is accorded to Dr. Miller of Berlin who was the first to produce caries artificially.

The chapter on the Treatment of Caries lacks lucidity and conciseness, while the classifications of diseases of the pulp and periosteum are meagre and not sufficiently up to date. Considering the large amount of literature which has accumulated around the subject of pyorrhœa alveolaris some reference at least to the more important papers is to be expected. We hardly think that the editors have given sufficient consideration to the investigations of Pierce, Kirk, and others on the question of certain varieties of periodontitis being due to the deposit of urates in the periodontal membrane.

There is an excellent chapter on Morbid Growths of the Teeth and Bland-Sutton's classification of odontomes is adopted. The chapter on Empyæma of the Antrum is good and contains much useful advice on treatment. The value of the book would have been enhanced by a fuller index.

LIBRARY TABLE.

Food Analysis. By HENRY LEFFMANN, A.M., M.D., and WILLIAM BEAM, A.M., M.D. Philadelphia: P. Blakiston's Son, and Co. 1901. Pp. 384. Price $2.50.—The value of a work upon food analysis depends chiefly upon the extent to which that work deals with modern methods. New and more accurate methods appear from time to time—almost day by day—in the scientific periodicals and those who have not access to periodical literature or do not avail themselves of it will be constantly finding out that they are employing methods which are obsolete or methods which give accurate results only after a tedious working. Even those possessing periodical literature on the subject find it inconvenient to seek out what may be new matter upon analytical method. The book before us is intended to help in this direction, being "a concise summary of analytic methods adapted to the needs of both practising analysts and advanced students in applied chemistry." Books of this type, however, need constant revision, so rapid is the advance of analytical chemistry. The authors' endeavour has been to collect most of the valuable matter relating to food analysis which has been published in official papers in the United States. However well they may have succeeded in this the fact that some of these methods though officially recognised in the United States are not so here will detract somewhat from the work as an authoritative guide on analytical methods in this country. The authors admit, however, drawing from the pages of the *Analyst*, the official organ of the Society of Public Analysts and many of the valuable works contributed by the members of that society. The chapter on Milk and Milk Products is much in a line with the very useful work issued conjointly by these authors on this subject some years ago. An admirable chapter on Colours is appended and a list of the colours permitted and forbidden by the National Association of Confectioners of the United States is added. Indeed, this chapter is a novel and valuable feature of the book. With the exceptions mentioned the book should serve as an excellent guide to students who are commencing the work of analytical chemistry as applied to food, and who have, of course, a knowledge of chemistry and of laboratory practice. It has been compiled with care and with the aim of making it a trustworthy source of reference in regard to modern analytical methods.

The Story of Wild Flowers. By Rev. Professor G. HENSLOW, M.A., F.L.S., F.G.S., &c. London: George Newnes, Limited. 1901. Pp. viii.-249. Price 1*s.*—In writing this work the author, to use his own words, has "tried to add something additional by putting life into those dry bones of structure" which generally forms the subject-matter of the ordinary text-book. Evolution is the thread running through the book. A feeling of disappointment was experienced in reading the volume, for the same fault is obvious here which is characteristic of so many popular works on science—that is, too much ground is covered and the facts given are too numerous. One result of this is that as examples many plants are cited which the reader probably will never see and which will, in fact, remain nothing more than mere names. For example, on page 115 may be found descriptions of Hiptage Metablota, Combretum argenteum, and Ipomæa argyræoides. Many writers of books on popular science seemingly lose sight of the fact that the knowledge of the subject possessed by the majority of their readers is practically *nil*, and hence it is difficult to appreciate a large portion of the information given. The facts generally are correct, although some inaccuracies may be found. For instance, on page 16 we find that collenchyma is described as a "hardened cellular tissue." It is doubtful whether botanists will agree with many of the author's interpretations of his facts. Our space is insufficient to enter into a discussion of them, nor, indeed, is it desirable to do so here. A useful appendix is added giving information as regards the place of origin, &c., of some of the commoner garden flowers.

Catechism Series: Botany. Part I. Edinburgh: E. and S. Livingstone. Pp. 88. Price 1*s.*—This work consists of a number of questions and answers, the latter condensed to the smallest possible dimensions: discussion and explanation are reduced to a minimum, prominence being given only to facts. This is obvious when it is remembered that the morphology, physiology, biology, and classification of plants are considered in 88 small pages. The facts are accurate on the whole. On page 14 we notice that Ranunculus ficaria (*sic*) is given as an example of plants which are propagated by means of bulbils which are described as "buds which separate from the parent and develop into new plants on the soil surface." In the description of the crocus corm we notice that no mention is made of the contractile roots. Many portions are inadequately considered, amongst others might be mentioned geotropism and the ascent of sap. In no sense of the word could the work be regarded as a text-book; as a cram-book it may find favour with many who desire to remember a few botanical facts for examination purposes.

Dopes. By NATHANIEL GUBBINS. London: Everett & Co. Price 1s.—After the recent stir made in the racing world on account of certain assertions in reference to the "doping" of racehorses it might naturally be expected that small books or pamphlets on the subject would in a short time make their appearance. "Dopes" is one of these, and its framework consists of a dissertation upon the racing world in general with a chapter thrown in upon "doping." By the term "doping" is understood the drugging of racehorses in such a way that they may be enabled to obtain greater speed for the time being or to last out a race; occasionally too, it is done to depress a horse so that he may not win. The principal drugs used include cocaine, nitroglycerine, various preparations of alcohol, opium, indian hemp, and bromides. It is needless to say that in the hands of the unscrupulous and untrained the administration of noxious drugs often leads to unforeseen and disastrous results. Cocaine in particular is an agent which, even in the hands of skilled veterinarians, has been known to give rise to peculiar and toxic symptoms. Some experiments made a few years ago by Professor Hobday, F.R.C.V.S., showed that even when this drug was used for surgical anæsthesia the idiosyncrasy of the animal was a factor which must always seriously be considered. Similarly with other drugs, overdoses give rise to disaster and the detected "doper" is not a man to be envied. The author of "Dopes" relates several instances which savour suspiciously of drug administration—one in which a five-year-old mare "seemed to go mad, knocked down and seriously injured a gatekeeper, ... and running 'amok' against the wooden fence which abuts on the racecourse, broke her neck." Doping is a criminal offence and, if only by opening the eyes of the general public a little to the rascalities which may be practised in this line, Nathaniel Gubbins may be said to have done something towards the eradication of illegal methods so commonly associated with racing.

New Inventions.

A SAFETY WINDOW-CLEANING APPARATUS.

IN THE LANCET of June 4th, 1898, p. 1543, we gave an account of a window-cleaner's chair invented by Mr. H. Gold and said: "In our opinion there should be no necessity for such an invention, inasmuch as in the interests of humanity local authorities should have the power, if they do not already possess it, of making it illegal for a person either to sit or stand on a window-sill above the ground floor of a building for the purpose of cleaning a window. Until such necessary laws are made, however, we welcome any device which will prevent or minimise danger to life or limb from this cause." The by-laws have been made, but we think that very possibly, like so many other laws made for the comfort and safety of citizens, they are no more enforced than are the laws about rolling casks, &c., on the footways between certain hours, or the laws about street noises. Windows in London must be cleaned; the majority of them are fixed except in a vertical plane and are too high for ladders to reach conveniently. Therefore, although a man may break the law by standing on the sill he will be able to do so without breaking anything else by using Mr. Gold's latest invention. As will be seen from the illustration it consists of a strong adjustable bar which fits diagonally across the window. To this are attached a strong rope and belt. Particulars of the apparatus may be obtained from Mr. H. Gold, 36A, Camomile-street, Bishopsgate, London, E.C.

THE LANCET.

LONDON: SATURDAY, JULY 27, 1901.

The British Congress on Tuberculosis and the Public Weal.

THE meeting of the British Congress on Tuberculosis which is taking place during the present week is being held under as favourable conditions as are possible while the Court is still in mourning and the country plunged in war. Many contend that such a Congress as the one now in our midst is of no practical utility. A heterogeneous gathering *is, they argue, not the place at which the results of serious* work should be brought forward. The tendency, they strongly affirm, is that any scientific paper read has usually been written for the personal glorification of the reader of that paper. Every man, they allege, has his own axe to grind, and wishes to grind it in public. To put the matter in its briefest form, they say it is "all advertisement." Others attack medical and scientific congresses from a different standpoint, but with no less vigour of invective. Science is serious, they remark; congresses are chiefly *social* arrangements which tend to become gigantic picnics, taking in vain the sacred name of Science. We do not agree with either of these views. But there is a substratum of truth in the statements that are so constantly made by the critical, so that it is fitting that we should state what are the benefits which we hope and believe will result from the Congress now sitting in London. This can be done quite briefly. We think that the communications which have been brought forward in the section devoted to the State and municipal aspects of protection from tuberculosis will be of great service to the public. The fact that the highest municipal representatives of some of the chief cities have taken an interest in these matters cannot fail to do good, and we look with the greatest confidence to the local authorities to give practical effect to the teaching which results from the laborious experiments of the men who have devoted their lives to scientific hygiene. To be of real use the knowledge acquired in the laboratory must be applied outside its walls. To do this falls within the scope of the municipalities Without their active help nothing effective can be accomplished, but we may feel sure that all our urban and rural authorities will recognise, after they have read the proceedings at this Congress, that activity in the prevention of tuberculosis will be expected from them, and that their efforts will be generally supported by those beneath their supervision. There are questions in regard to the prevention and treatment of tuberculosis which it is to be feared are still beyond a measurable distance of settlement, but the work of the Congress will, it is hoped, do much to focus the attention of the public on certain important matters which concern their welfare and which depend for fulfilment on themselves alone. A knowledge by the people of the facts concerning the origin and mode of spread of tuberculosis cannot fail to be of use to them. When the facts are appreciated it will ultimately fall on the people to decide whether or not in the public interest all cases of tuberculosis should be notified in the same manner as that which is adopted in the case of some other diseases. Some of the refinements of bacteriological teaching will be regarded by the public as analogous to the theological discussions of the middle ages, and therefore best left to those whose mental constitution finds pleasure in them. This is well. There is no need for laymen to take any interest in such details. What is necessary is that it should be more generally understood that certain facts have been definitely established—e.g., that tuberculosis may be communicated from one person to another; that the infectious matter is capable of being conveyed by the sputa; that light, fresh air, and high altitudes are generally beneficial; that houses should be kept clean and well ventilated; *that well cooked and nourishing food forms a suitable diet*; and that intellectual stagnation is good for no man. If the public in their millions, whether at first hand through the press reports or more remotely from conversation with their fellows, can learn these simple lessons from the Congress, an enormous stride forward in practical sanitation will have been accomplished.

Professor Koch's Address at the Congress on Tuberculosis.

THE remarkable address which was delivered before the British Congress on Tuberculosis at the second general meeting by Professor KOCH cannot fail to attract attention throughout the medical world. And this not merely because of the personality of the speaker, whose presence at such a gathering was singularly opportune—for is it not to his genius that we owe our knowledge of the true nature of this widespread disease?—but because the message which he had to deliver was full of hope in a successful issue of the struggle against this prevailing scourge. Upon such a subject Professor KOCH speaks with an authority which none can dispute, and we may be sure that he would say nothing that was not based upon sound data. Nor does he admit that finality has been reached. With characteristic modesty he details his latest investigations and asks that others should take up this line of inquiry in order that the inferences which he has drawn from them may be confirmed or refuted. If they are confirmed the gain will be enormous, for the measures taken for the prevention of tuberculosis amongst mankind will be restricted within far narrower limits than the results of commissions and the laborious investigations of comparative pathologists have led us to believe that they could be. With this brief reference to the topic which seems to us to stand out prominently from all other parts of this noteworthy utterance we may follow Professor KOCH in his arguments, noting that they are marshalled with the method and enumerated with the lucidity to which all his deliverances have accustomed us.

In regard to its main theme the address was, as we have said, most hopeful, indeed optimistic, in tone. It was the expression of conviction that, now that we clearly apprehend the nature of tuberculosis the lines can be laid down for its prevention and eventual extirpation. No longer considered to be generated, however much it may be fostered, by conditions of "social misery," or to be transmitted by inheritance—except in the rarest cases—it takes rank with many another acquired disease which, like it, is essentially parasitic in nature. But various diseases are, as Professor Koch reminds us, not to be combated by measures of the same type. We must know the etiological circumstances in each one separately and modify our lines of prophylaxis accordingly. We may group them all as infective disorders, but before we can successfully cope with them we must rightly understand in what way they are infective—in other words, by what means the parasite is conveyed to the human being. He cited the cases of plague, cholera, hydrophobia, and leprosy to show how no general set of preventive measures is applicable to check their spread, but that in each the particular mode of transmission has to be reckoned with. Thus human plague, except in its comparatively rare pneumonic forms, is now known to be mainly transmissible from the rat, and no matter how elaborate the measures to prevent infection it will not be stayed if this necessary factor be overlooked. Cholera is mainly diffused through the medium of water-supply and its preventive measures must have the regulation and purification of potable water for their aim. Hydrophobia cannot be hindered from spreading so long as the infected dog is suffered to roam about unmuzzled. Leprosy, in some respects akin to tuberculosis and transmissible from man to man living in conditions favouring close contact, is shown to be scientifically most effectively prevented by the segregation of the worst cases, thus following on the track of the system which in the pre-scientific era led to its banishment from Central Europe and from this country.

With these examples before him Professor Koch next proceeded to inquire into the methods whereby infection of human beings takes place in tuberculosis. We venture to say that if this question had been put to the members of the Congress prior to their listening to this address there would have been an almost unanimous opinion that it was transmitted in two main ways—(1) by inhalation of dust containing tubercle bacilli; and (2) by the ingestion of food-stuffs, especially milk and flesh coming from infected animals. Professor Koch admits the first in its entirety, but he deals a staggering blow to faith in the second alternative. This is so important and far-reaching a view that it demands a thorough reconsideration of the whole question of the transmissibility of tuberculosis from animals to man. Indeed, if Professor Koch be right, time may prove that the labours of one whole department of this Congress have been thrown away and will come to be regarded as an example of misdirected science at the dawn of the twentieth century. Professor Koch reminded his hearers that in his earliest researches he was somewhat sceptical as to the identity of human and bovine tuberculosis. His most recent work has almost, if not quite, changed his doubts into certainties. Our readers can glean for themselves the facts which led him to this conclusion. Summarily they may be said to depend on the experimental test that tubercle-free bovines (and other animals, such as swine, asses, sheep, and goats) are immune to infection—whether by inoculation or in other ways—as far as regards human tuberculosis, but singularly vulnerable to the bacilli of the bovine disease. And he appeals in confirmation of these results to the older experiments of others as to the insusceptibility of cattle to human infection and urges that the inquiry should be taken forward, as we do not doubt it will be on all sides. The German Government has already appointed a Commission with this object. Of course, Professor Koch admits that because bovines may be insusceptible to human tuberculosis it does not follow that the converse is the case, and experiment is out of the question in this respect. But he declared with a boldness which compels admiration, since it runs directly counter to teachings which we have had from all quarters in the past decade, that there is very little evidence of tuberculous infection by way of the intestinal tract. He cited statistics from the Charité Hospital and other hospitals to show the rarity of intestinal tubercle in children apart from pulmonary and bronchial tubercle, and he inferentially led his hearers to believe that all such cases are explicable on the view that occasionally human tubercle bacilli may be swallowed rather than inhaled. But he goes farther and tells the sceptics that their doubts can be set at rest by an appeal to the experimental test. If the disease in the human subject be of bovine origin, then the cultures of bacilli from its foci will transmit the disease to a bovine inoculated with it: but if it be of human origin this test will yield a negative result. Here then we have a clear issue and one which, in the interests of the community, as well financially as socially, will, we hope, be definitely determined before long.

Setting aside this question of transmissibility from animals, which we consider more in detail in the article which follows, there is ample scope for preventive medicine in checking the ravages produced by infection through the ordinary channels. Professor Koch shows us how closely this subject is linked with that of the housing of the poor; how under the prevailing conditions of overcrowding in great cities the means for infection not only of families but of dwellings are only too clear; and he paid a well-merited tribute to the work set on foot in this direction by Dr. Hermann Biggs of New York. He also pleaded for more special hospitals, or, at least, for special wards for consumptives, and attributed much of the decline in the disease in this country to the fact that we have so many of these institutions. Notification, disinfection, and the dissemination of knowledge of the nature of the disease amongst the people were other measures from which he hoped much good to accrue, whilst he bade the Congress not to be too sanguine as to the results to be expected from sanatoria, although he said enough to show the value of their work in limiting foci of infection and in increasing the proportion of recoveries of those attacked by the disease. All must feel that this address was worthy of the occasion and of the eminent leader in epidemiology by whom it was delivered.

Professor Koch and Tuberculous Milk and Meat.

"Though the important question whether man is susceptible to bovine tuberculosis at all is not yet absolutely decided, and will not admit of absolute decision to-day or to-morrow, one is nevertheless already at liberty to say that, if such a susceptibility really exists, the infection of human beings is but a very rare occurrence. I should estimate the extent of infection by the milk and flesh of tuberculous cattle and the butter made of their milk as hardly greater than that of hereditary transmission, and I therefore do not deem it advisable to take any measures against it."

Already, before these memorable words of Professor Koch could be published in The Lancet, they had carried solace or given rise to astonishment, and even incredulity, in most parts of the civilised world. Their effect it is at present impossible to estimate. If they are true there would seem no reason, *quâ* tuberculosis alone, why we should not consume raw tubercle-riddled udder and give to our children milk drawn from similar sources. The truth, however, must survive, and it remains for us to decide wherein is truth. It would have been difficult for our distinguished and honoured guest to have chosen a more fitting or a more dramatic occasion for his remarkable announcement, seeing that not a little of the labours of the State Section of the Congress is concerned with the control of our milk and meat supplies. Accustomed as we are to accept the researches of Professor Koch almost without demur, we feel, nevertheless, a little staggered by the directness and conclusiveness of the statement which prefaces this article. That statement has for its support much evidence; and the results of a series of experiments performed by Professor Koch and by Professor Schütz of the Veterinary College in Berlin during the last two years are calculated to make us pause. Briefly stated, they are as follows. Two series of young cattle were taken and tested with tuberculin and were concluded to be free from tubercle. The members of one series were inoculated with, and made to inspire, bovine tubercle, those of the other series were infected with tubercle of human origin. The first series was attacked by tuberculosis and the second remained free. Similarly an analogous experiment was made with two series of swine and almost identical results were obtained; but there is this exception—a straw indicating something—"here and there little nodules in the lymphatic glands of the neck, and in one case a few grey nodules in the lungs" were found. Asses, sheep, and goats, into the vascular system of which the two kinds of bacillus were injected, behaved in the same manner as bovines.

Professor Koch's address is published in full in our columns and we feel sure that all will agree with him that "it seems very desirable that these experiments should be repeated elsewhere in order that all doubts as to the correctness of my assertion may be removed," and it is clear to us that the duty devolves forthwith upon the Government of this country. If Professor Koch's experiments are confirmed, and those who confirm them are able to draw similar inferences therefrom, a very marked change must occur in our methods of sanitary reform. If we can, according to Professor Koch, consume bovine tubercle with impunity it is clear that much meat and milk have been wasted. In this country alone there have recently been two Royal Commissions upon the question of tuberculosis. One Commission decided, upon experiments done at its instigation by Dr. Sidney Martin, Professor Sims Woodhead, and others, that the inference was justified that danger attached to the consumption of tuberculous milk and meat; the other laid down some useful precautions arising out of these inferences. According to Professor Koch the inferences are unsound, as also are the deductions based upon the behaviour of tabes mesenterica in infants and the conclusions as regards the accidental inoculation by bovine tuberculosis of persons engaged in the care and slaughter of tuberculous animals. These cases are recorded by Professor Nocard of Alfort, a delegate from France to the Congress, in his work on "The Animal Tuberculoses and their Relation to Human Tuberculosis." But assuming the series of experiments which were performed by Professor Koch to have been in every way satisfactory, are the inferences which some will draw therefrom justified? Is it safe, in view of the serious consequences at stake, to assume that, because human tuberculosis is not communicable to bovines, the converse of the proposition—that bovine tuberculosis is not communicable to man—holds good? For our part, we must hesitate to affirm the proposition. The well-known difficulty of the communicability of small-pox to bovines and other similar phenomena must make us critical, as also must the fact that in inoculating human tuberculosis into bovines we are inoculating with a virus possessing a lower degree of virulence than is possessed by bovine tuberculosis. Is it, too, established beyond a doubt that pulmonary tuberculosis is always air-borne? These points and many others were raised by Lord Lister after Professor Koch's address in a manner worthy of the highest traditions of English science and courtesy. We possibly incline to the view that the harm wrought by tuberculous meat has in the past been a little exaggerated by certain medical officers of health, but to pass from this to what amounts to a negation of any harm from tuberculous meat or milk is a somewhat heroic stride, and, as Lord Lister remarked, it is "a serious matter if the conclusion be wrong." How serious in the direction of putting back reform in our meat and milk traffic, those who are familiar with the excuses of sanitary authorities for a policy of inactivity can judge.

Lord Lister's advocacy of caution was entirely endorsed by such observers as Professor Nocard, Professor Bang, and Professor Sims Woodhead. But their criticisms, though weighty, are under the circumstances insufficient. On all sides our medical officers of health will be met with the difficulty which has been raised, and with sanitary authorities, as doubtless with magistrates, the utterances of Professor Koch will carry, as well they may, a weight which nothing but a repetition and extension of the experiments in question can affect. We therefore trust that the British Congress on Tuberculosis, which has opened under excellent auspices and from which much is expected, will make it one of its duties to press upon the Local Government Board and the Board of Agriculture the enormous importance of at once acting upon Professor Koch's generous and thoroughly scientific suggestion that his results should be forthwith checked. In our view the Congress will fail in its duty if, after having been largely responsible for raising this great issue, it neglects at least to instigate the Government towards a speedy solution of the matter.

Annotations.

"Ne quid nimis."

THE FIRST REPORT OF THE ROYAL COMMISSION ON ARSENICAL POISONING.

WE regard with satisfaction the decision of the members of the Royal Commission on Arsenical Poisoning to report their proceedings from time to time and to summarise in a series of reports the conclusions at which they have arrived from evidence already at hand. The first report has just been published and relates chiefly to that part of the subject—viz., arsenic in beer—which first gave rise to the expediency of a Parliamentary inquiry being instituted to examine into the whole question of arsenical contamination of food. We approve this course strongly, especially in the present instance, even at the risk of some of the conclusions being premature, for the recent epidemic of poisoning by beer was a most serious occurrence and such as naturally caused considerable alarm. It was the obvious duty of the Government to allay this alarm without delay, to check the evil, and to prevent its recurrence. But as a matter of fact, as the commissioners in their first report acknowledge, when beer was discovered to contain arsenic steps were immediately taken by brewers and by sanitary authorities to ensure that this arsenical beer was withdrawn from sale, and this was done usually with commendable rapidity and as a result the epidemic came speedily to an end. Such a satisfactory termination was evidence of an intensely practical kind that—to adopt in part the phraseology of the terms of inquiry of the commission—(1) the amount of recent exceptional sickness and death was attributable to poisoning by arsenic, and (2) that such exceptional sickness and death were due to arsenic in beer. The Royal Commission, after hearing the evidence of over 50 technical and expert witnesses, have, of course, come to the same conclusions. Their duties, however, by no means cease here. They have yet to consider the apparent ubiquity of arsenic, by what safeguards the introduction of arsenic into foods and countless other things besides beer can be prevented, and whether it is practicable to keep out arsenic altogether or if not to decide what amount of arsenic in food may be safely regarded as negligible, and what methods of analysis may be relied upon to determine such limitations Thus there are many important points left for future determination and this is frankly acknowledged in the first report. The Royal Commissioners propose to make further inquiry into the relative value of quantitative tests, and in the case of beer as to the possible existence of arsenic in it in some combination with organic matter which defies detection by the ordinary tests. They hope also to obtain further facts in regard to the many important medical and toxicological aspects of the epidemic, and by inviting the coöperation of public analysts throughout the country, and in other ways, to obtain further information with regard to arsenic in articles of food and drink other than beer. Further inquiry also must be instituted before a standard test, should it be decided to impose one, can be recommended. Lastly, it is evident that amendments in regard to administrative measures have to be considered, not only with reference to the question of arsenic in beer, but also in relation to the broader question of the machinery available to public health authorities to obviate the risk of arsenic or other poisonous substance gaining access to articles of food and drink in general. At present it is impossible to make final recommendations upon this important general question. The commission, however, think that as a provisional measure the machinery under the control of the Board of Inland Revenue might effectively be turned to account to check the introduction of arsenic into beer by way of its ingredients. To this end they recommend that the Board of Inland Revenue should possess, and should exercise, powers to specify in detail those individual ingredients of beer which are liable from their origin or mode of preparation to be contaminated by arsenic; to prescribe for all such ingredients, and for the different materials used in their preparation, an adequate test which should ensure their freedom from arsenic; and to prohibit under penalty the use in a brewery of any material which infringes the prescribed test. Dr. B. A. Whitelegge demurs to the wide terms of this recommendation, since, as he points out, they include the more remote materials which are not to be found in the brewery or in the sugar factory—such, for example, as the fuel which has been used in the malting. There is much to be said in favour, we think, of limiting this control to ingredients actually coming into the brewery which excise officers can sample and submit to the Government laboratory for analysis. A certificate of analysis from the vendor, it is well to remember, would only be a guarantee of the particular parcel of fuel from which the sample was taken. Clearly, if the kiln-dried malt is free from arsenic the fuel used for the purpose must have been free from reproach. The Royal Commission have begun their work well. They have yet many vexed questions to elucidate which will need considerable patience and considerable work, but their first report leads us to look forward hopefully to a satisfactory conclusion being arrived at as far as is possible having regard to the great number of knotty points which the inquiry involves.

THE "DOPING" OF RACEHORSES.

IN another column we have briefly reviewed a small work on the above subject which has recently been published for the lay reader. "Doping," or drugging, is supposed to be done to a much greater extent in America than in England, but in either country it can only be practised at racecourses where the rules are lax or the morals are of the lowest possible kind. For temporarily increasing the speed stimulants containing ether or alcohol used to be given, but these are difficult to administer without detection and have now been almost entirely superseded by the hypodermic use of cocaine. The effect of the latter upon horses and dogs has been made the subject of numerous experiments by Professor Hobday, F.R.C.V.S., a leading article on whose work (published in the *Journal of Comparative Pathology and Therapeutics*, vol. viii., p. 20, and vol. x., p. 80) appeared in THE LANCET of August 31st, 1895, p. 533. This observer found that in medicinal doses cocaine acted temporarily as a strong stimulant to the muscular system and this was well exemplified by the use of hypodermic injections in cases of chorea; in dogs affected with this troublesome disease the twitchings disappeared entirely whilst the drug maintained its influence, but the after-effect was bad, the patient being perceptibly weakened. After large or over-medicinal doses both horses and dogs became very much excited and quite frantic, it being impossible permanently to keep the subject still. This stage of hyperæsthesia is the one which the "doper" wishes to avoid, for until the effects began to pass off, it would be quite impossible for the movements of the racehorse to be controlled. Besides, the wild appearance of the eye, the curious twitchings of the muscles, even if the animal was brought to a standstill, would at once give rise to suspicion. That the "doping" of racehorses is wrong in principle goes without saying, as from no point of view can it be defended. A horse should win entirely upon its own merits without the aid of artificial stimulants, quite apart from the bad after-effect which such drugs have upon the system when they are frequently used. In addition to the drugs which stimulate the use (generally for dishonest purposes) of those which depress or narcotise must not be overlooked. Of these opium and bromides are the most common, or even a dose of purgative medicine may be resorted to. The "doping" of racehorses is a crime which is punishable by law in addition to the social ostracism which would inevitably follow detection of the persons who used such means, and it is a practice which we are thankful to say cannot be considered at all common in our country.

THE SALE OF INTOXICANTS TO CHILDREN.

IT can hardly be doubted that the great majority of persons who have really given their attention to the subject are agreed that the Bill to prevent the sale of intoxicants to children should find its place in the statute-book. There is no question that children are employed in fetching liquor from licensed houses a great deal more than is advisable for their own good. Accurate statistics are hardly necessary to assure us of this fact, but recent evidence of this kind, if it be desired, is not wanting. In a letter published in the *Times* of June 4th the Marquis of Northampton quoted details of a series of observations bearing on this point. These included the following. On a Saturday between 9 P.M. and midnight 200 public-houses in four districts of London were under observation and a total number of 7019 children were seen to enter them. A respectable house in a quiet street was seen to be entered within the same hours by 26 children and 225 adults. A low-class house during the same hours was visited by 201 children and 1282 adults. These particulars may be regarded as illustrative of Saturday evening trade in London. In another town of 117,000 inhabitants 12,000 children were seen to enter licensed premises on a Saturday during four consecutive hours. The figures relating to one house observed during the seven legal hours on a Sunday are even more remarkable. The number of adults entering was 2558; that of children was 1365. Of the latter 706 were noticed to enter between 1 P.M. and 3 P.M. and 369 between 7 P.M. and 9 P.M.—that is to say, about the times when beer would be in demand for the family meals. Children according to the terms of the new Bill are young persons under 14 years of age. The statistics just quoted refer as nearly as could be judged to young people under 16 years of age, the average being 10 years. Where there appeared to be reasonable doubt as to the age the child was not counted. The Standing Committee of the House of Commons which is now occupied with this subject held a meeting on Friday, July 19th. As regards the expediency of the Bill itself no question was raised, but an amendment was moved in the name of Sir Lewis McIver to allow the sale to children of liquor in corked or closed vessels. This was carried by a majority of one. A further amendment moved by Sir W. Houldsworth to substitute the words "corked and sealed" for "corked or closed" was also adopted. There appears to be some ambiguity here in the proposed wording of the Bill which it is highly desirable to have rectified. A corked and sealed vessel is a definite object enough, a "closed" vessel might be made to denote almost any kind of receptacle. It might be a jug with a moveable lid or a pot covered in with paper. In either case the proper object of the Bill—namely, to remove from children as far as possible the temptation to help themselves to an intoxicant—would be virtually set aside. For this reason we trust that if the amendment is to stand as part of the Bill any existing uncertainty will be entirely removed and that care will be taken to have any vessel carried by a child properly corked and sealed. It is also to be remembered that much of the good which the Bill is intended to do will be done away with if its wording is not so framed as to require that children shall not be served at the ordinary bar but in a separate department. "Sipping" which some affect to scoff at, though it must often have led to freer indulgence, is only a part of the evil which it is sought to remove. The atmosphere of a bar-room with its frequently rowdy associations can hardly fail to exercise a mischievous effect on young people at the most impressionable period of life. But what, after all, is the practical value of this amendment in favour of the off-licence? To us, indeed, it appears to give little promise of practical utility and we should not be sorry if it were excluded. It is almost certain that the great majority of children who enter public-houses are sent, not for liquor in bottle, but for dinner or supper beer or for small quantities of spirits. It is difficult to see, therefore, what the amendment will do even for public convenience. There might, perhaps, arise an occasion, such as an emergency of illness in which no other messenger but a child was obtainable. In most cases of this kind, however, some adult neighbour would usually be at hand and the services of such a one would certainly be preferable. With the possible exception of such an occasion for which a special arrangement might be made we cannot see where the necessity should exist for the employment of children at all as carriers of liquor. We have noted that the limit of childhood for the purposes of the proposed Act is 14 years. We hope to see this age raised to 16 years. No hardship would be thus inflicted, and we believe that a fairer standard would then be realised of the period at which independent responsibility should be recognised.

CÆSAREAN SECTION THREE TIMES IN THE SAME PATIENT.

IN the Journal of the American Medical Association of June 29th Dr. J. W. Coakley has published the following remarkable case. A woman, aged 30 years, was in labour on August 3rd, 1893. In two preceding labours craniotomy had been performed for contracted pelvis. The conjugate diameter was two and a half inches. An incision was made in the abdominal wall from four inches above the umbilicus to two inches above the pubes. The peritoneum was opened and the uterus was lifted outside the abdominal cavity. A rubber ligature was passed around the uterus to prevent hæmorrhage. An incision four inches long was made into the uterus and the child was removed with the membranes intact. The uterine and parietal wounds were sutured. Recovery was uninterrupted. The patient was again in labour at term on July 27th, 1895. The placenta was attached near and over the os uteri. Cæsarean section was again performed: the cicatrix of the former operation was cut through and the wall of the uterus was found to be very thin. The membranes were ruptured and the child was removed. The placenta was removed and the adherent portions of the decidua were separated. Recovery was again uninterrupted. In February, 1900, the patient was in the eighth month of pregnancy. She was in poor health; the urine was loaded with albumin and there were headache and other symptoms of renal insufficiency. Labour began on March 2nd, but Dr. Coakley was absent and could not operate until the following day. On cutting through the abdominal wall at the side of the old cicatrix the peritoneum was found adherent to the uterus and also to the abdominal wall.

The adhesions were broken down and the uterus was lifted out of the abdomen. Dr. Coakley did not on this occasion pass a rubber ligature around the uterus, having abandoned the procedure on the ground that if tight enough to control the hæmorrhage the ligature would injure the uterus. In 13 minutes the operation was completed except for the tying of the abdominal sutures. Recovery was rapid, the only complication being a temperature 1·5° F. above normal on the fourth day. On the twentieth day the patient was removed to a house three miles distant.

THE CHEAP PISTOL.

THE *Times* of July 22nd contained a report of the inquest upon a youth, aged 19 years, who had committed suicide, after expressing in shorthand upon the margin of a novel by a popular lady author his approval of a phrase which he had found in the mouth of one of her characters that "suicides have no souls." On what grounds suicides were to be thus distinguished from their fellow-men does not seem to have been discussed either by the lady novelist or by Harold Paris, but the boy, having been apparently impressed by the profundity of an observation which seems to us meaningless, and having resolved to die in the company of a penny novelette and "The Romance of Two Worlds," found no difficulty in providing himself with a suitable weapon. Had he tried to drown himself or to stab himself to death his resolution would possibly have failed him—had he tried to buy a sure but painless poison he would have encountered difficulties in making the purchase; but a postcard found among his effects showed that a Birmingham firm was able to supply him with a pistol for the sum of 3*s*. 3*d*., and it may have been, although it was not so stated at the inquest, that the 50 cartridges also possessed by him were bought at the same time and included in the same payment. The sale of cheap revolvers from time to time engages the transitory attention of Parliament, but the House of Commons shrinks apparently from interfering with the maker of cheap pistols, whether at home or abroad, and with a trade that is practically confined to toyshops. It has often been pointed out that a tax that would hardly affect, or which could be remitted from, the more expensive revolver used in warfare would entirely shut out of the market the gimcrack weapons that are now a source of danger to their usually youthful owners, to the friends of those young persons, and to innocent persons residing in their neighbourhood. Not a week passes but we see, not perhaps an account of deliberate murder or suicide by shooting, but an account of a pistol accident, or a wound inflicted in a quarrel by some young rowdy on some person against whom he has had a grudge or who has been passing by when he chose to fire or when the pistol went off in his irresponsible hands. Many more such cases are, no doubt, hardly reported or heard of; the calendar, however, of charges at the Old Bailey, published on the same day as the newspaper to which we have referred, contains two cases of attempting to murder with the pistol and, without doubt, it would be pretty safe to wager that the value of the two weapons alleged to have been used will not be found to amount to a sovereign. Can a trade which supplies these always dangerous, sometimes deadly, weapons be worth protecting? It is true that murders and suicides are perpetrated with the help of knives, razors, hammers, drugs, and other inanimate agents, but all these have uses of their own which are obvious and their abuse cannot altogether be prevented. The cheap revolver has no use. It is not a sporting weapon, it is of little or no effect as a protection against violence, while the householder who believes that he needs some such protection could afford to pay the tax on revolvers that we have contemplated and to purchase at the same time a superior weapon, although we must add that, as a rule, revolvers are more dangerous to the occupants of the house than to the intrusive burglar. Skill in the use of the toy pistol is not a prelude to skill with a weapon of use in war, for the schoolboys who buy toy pistols do not cultivate their aim by practice at marks, and revolvers are of little or no use in modern fighting. Such weapons as that with which the boy of whom we have written killed himself are simply dangerous and their danger is not confined to those who use them and to the circle of their friends and playmates—it is shared by those who have no acquaintance with the person who causes the discharge. As a means of committing suicide the cheap pistol has the merit of not being infallible, but it attracts by its reputation for causing a speedy death and possibly by its association with the phrase "blowing his brains out," which figures largely in the literature that the brainless peruse.

THE HEALTH OF CANNES.

THERE has been a good deal of typhoid fever all along the Riviera from San Remo to Marseilles during the last two or three years and it is very interesting to note how, having spared Cannes so long, an epidemic has at length declared itself at that place. There are four factors to be considered as influencing the sanitary condition of Cannes—(1) the water-supply, (2) the main drainage system, (3) the floricultural industry with its incessant irrigation and manuring, and (4) the turning up of considerable areas of earth. As regards the water-supply Cannes has a supply of most excellent water which comes straight from the limestone hills above Grasse some 30 miles away. Unfortunately it is brought in a canal which is practically uncovered and passes through or near many villages or farms from which fæcal pollution is quite possible. For more than 20 years the English medical men at Cannes, supported by one or two of their most scientific and far-seeing French colleagues, have been pressing upon the town council the necessity of either covering in this canal or making another for supplying the town with pure drinking-water in pipes. They have so far succeeded that a plan is now before the town council for bringing a supply of pure water in pipes from the river Loup which is not very far from Cannes and the water of which is beyond suspicion. But, as usual, there are many members of the council who are unwilling to spend money except for additional amusements, or theatres, or a casino, or ornamental buildings, or advertisements which they suppose will attract strangers to Cannes. The main drainage system which was undertaken by the town council under great pressure from the English residents and medical men, has never been completed. The intercepting drain, which was to have been furnished with powerful pumps and to have conveyed the sewage to be discharged into a deep current of the sea at a safe distance from the town, has never been made; the various collecting drains therefore discharge into the bay of Cannes at a short distance from the shore. There is, too, no proper supervision of the junction of house drains with the main drainage system. The natural vegetation of Cannes and the Riviera consists of olives and fir trees. These flourish with comparatively little water. They are gradually being used up for fuel and their place is being taken by florists' flowers which now form the chief industry of the coast and which require constant irrigation and manuring (partly with human excreta, the contents of cesspools, and the like). All along the Riviera during the last few years there has been a great deal of earth-turning and road-making which has brought to the surface much sewer-tainted earth, and this seems to have opened the door in some way to the epidemic of typhoid fever. The construction of roads and sewerage at Mentone was followed by the outbreak of typhoid fever.

The making of new roads and houses at San Remo was accompanied by typhoid fever from which two of the English medical men suffered. At Antibes the old fortifications were levelled and typhoid fever appeared; at Nice the excavations for the large hotels, the new drainage, and the railway to Grasse were followed by a great outbreak of the disease; and now at Cannes where a large surface of sewer-polluted land has been turned up for the railway works and the building of the Palais de Justice this outbreak of typhoid fever takes place. About 20 years ago the Crédit Lyonnais made an immense boulevard from Cannes to Cannet and a large area of earth had to be upturned and at that time occurred the last epidemic of typhoid fever. With regard to the immediate cause of the present outbreak the French medical men are divided. One party declare that the fever is nothing, that it is not typhoid, and that it cannot be due to water pollution and will not allow that money should be expended on such useless improvements as drains and waterworks; the other party, more broad-minded, think that they have traced the outbreak decidedly to the water-supply and are doing their best with their foreign *confrères* to hasten the completion of the new drinking-water canal Probably the epidemic has been led up to by various circumstances and conditions which are common to the whole Riviera. The effluvia which have been constantly at work from the use of human excreta for manuring the plants, from the turning up of sewer-polluted ground, and the smells from the badly kept dairies have reduced the power of those exposed to them to resist any typhoid poison. This poison has been supplied either through the drinking-water or by the eating of uncooked vegetables and fruit which have been watered with human excreta, or perhaps by typhoid germs blown from the innumerable establishments of horticulture which poison the beautiful air of the Riviera in all its most desirable quarters. Cannes would be the healthiest town on the Riviera if only—(1) the drinking-water could be conveyed in pipes; (2) the main drainage could be finished and the pumping machine brought into use as proposed; (3) the dairies could be properly supervised and the stalls kept cleaner; and (4) proper laws could be made to regulate the manuring of the floricultural establishments: (*a*) as to the hours during which the manures might be applied; and (*b*) as to the covering of the manure with earth or mixing it with disinfectants when it is applied

THE DISTRIBUTION OF PLAGUE.

A TELEGRAM from the Governor of Cape Colony, received at the Colonial Office on July 18th, states that for the week ending July 13th the cases of plague at the Cape were as follows: Malays, 2; native, 1; Europeans, coloured persons, Indians, and Chinese, 0; total 3. There were no corpses found. The deaths are as follows: 2 occurred among Malay and none among other nationalities. The total cases of plague up to July 13th were: Europeans, 185, coloured persons, 330; Malays, 61; Indians, 11; Chinese, 1; natives, 142; total 730. The total deaths for July 13th numbered: Europeans, 43; coloured persons, 175; Malays, 44; Indians, 9; Chinese 0; natives, 61; total, 332. At Port Elizabeth the cases for the week ending July 13th were: Europeans, 1; coloured persons, 1; natives, 3; total, 5. One coloured person died. The total cases to July 13th were: Europeans, 7; coloured persons, 5; Indians, 1; Chinese, 1; natives, 14; total, 28. The total deaths numbered 10, and the total cases of plague at all other places were 10, of which number 5 were Europeans. A second case of plague in an Indian from the remount camp at Port Elizabeth has occurred among persons under naval and military control and the area of infection remains unchanged. A telegram from Mauritius, received on July 19th, states that in the week ending July 18th a fatal case of bubonic plague occurred. As regards Egypt, for the week ending July 14th only 3 cases of plague and 1 death from the disease have occurred throughout all Egypt. Zagazig furnished these cases. The present situation with regard to the plague in Egypt may be considered extremely satisfactory, and we trust that before long the disease will have completely disappeared. The disinfection and cleansing of the towns infected, it appears, are being thoroughly carried out. In Hong-Kong for the week ending July 20th there were 13 cases of plague reported and 16 deaths.

THE PROPOSED LEGISLATION ON BAKEHOUSES.

OF course it is to the interest of the public at large that the bread which we consume should be made in clean and wholesome bakehouses, but some consideration should also be given to the comfort and health of the journeymen bakers who are engaged in kneading our daily supply. It is possible, though perhaps not very probable, that an underground bakery may be quite clean and that there may be no open drain in its immediate vicinity. On the other hand, the efficient ventilation of an underground bakery must be a matter of great difficulty and the room is not likely to be sufficiently lofty. The insanitary conditions of such bakehouses were described and denounced in a report by our Special Commissioner which was published in THE LANCET of Nov. 30th, 1889, page 1140. We then also stated that the secretary of the Journeymen Bread and Biscuit Bakers' Pension Society informed us that 14 out of 18 men, then receiving pensions, were more than five feet eight inches in height. This was no exception but the general rule. A short man's head would be in the line of the draught going to the oven furnace. A tall man's head would be above this draught and nearer the ceiling where the vitiated air stagnates. In view of this circumstance there should be apertures or ventilating shafts along the ceilings. In any case the bakehouses should be lofty so that even tall men would not respire from the layer of vitiated air. Naturally, it is much more difficult to obtain such conditions in a cellar than in a bakehouse built above ground. The other disadvantages of underground bakehouses are better known and appreciated by the public at large and have been often denounced, so that altogether there can be no question but that their total abolition would be a great boon to the public in general and to the journeymen bakers in particular. We are therefore pleased to note that the Government Bill to amend the Factory and Workshop Act proposes in Clause 28 that after Jan. 1st, 1904, underground bakehouses shall not be used unless certified by the district council as suitable for that purpose. "Underground" is defined as a room with a floor that is more than three feet below the level of the roadway, but even such bakehouses will not be abolished if they obtain a certificate. The worst of this enactment is that its success depends on not only the energy but also on the technical knowledge of the district councils. If such a matter is left to their discretion, many abuses, we fear, will still survive and there will be no uniformity. A committee of experts should draw up model plans, giving illustrations of typical cellar bakehouses and showing how these can be altered in a satisfactory manner; for it seems to be the opinion of the framers of the Bill that this is possible. Certainly, we can conceive that a bakehouse which has its floor four feet instead of three feet below the level of the street might be fairly ventilated and healthy if the wall, or rather the ceiling, was six feet above the street. In these six feet of space above ground, four feet of which would be above the head of a tall man, a thorough draught might be established and effective ventilation secured. But will all the district councils be technically capable of securing these advantages, unless they are taught and stimulated to take energetic action by a more competent central authority? In any case, some good will undoubtedly result, though its extent will vary in different places, according to the intelligence and activity of the local authorities. Yet an attempt was made to delay even this measure of reform, and it was proposed that Clause 28 should not be applied till Jan. 1st, 1906. Fortunately, Mr. John Burns energetically opposed such adjournment, and quoted some of THE LANCET reports to show how great were the existing evils. Sir Henry Fowler and other members of the Grand Committee of the House of Commons, we are pleased to see, supported Mr. Burns, and finally Mr. Ritchie declared that he would adhere to the date originally proposed—namely, Jan. 1st, 1904.

EQUINE SUN-BONNETS.

THE use of the sun-bonnet as a head covering for the horse during the intense heat of summer is much more noticeable this year in our streets than it has been previously. The idea is unquestionably a good one and, although it was very much ridiculed some two years ago when it was first introduced, it has undoubtedly come to stay. Several of our great omnibus companies and the owners of other large studs have adopted them universally, and the general consensus of opinion is that cases of sunstroke and heat apoplexy are of much less common occurrence in consequence. In devising a sun-bonnet there is no need to carry the idea to an absurd point; what is really needed is a covering slightly raised from the head which will protect the poll and base of the brain from the direct rays of the sun. The ears should be left free, and ribbons and tassels, although perhaps adornments, are not a necessity. Straw seems to be the favourite material, but we have seen several very good patterns made up of light calico spread over a wire framework. As equine sun-bonnets can be obtained for as small a sum as 2¾*d.* (with a probable reduction on taking a quantity) the cost is not prohibitive and there is no reason why the coster's donkey should not be as effectually protected as the gentleman's carriage-horse.

ANKYLOSTOMIASIS.

MR. C. LE NEVE FOSTER, D.Sc., F.R.S., in his report just issued for 1900 as His Majesty's Inspector of Mines for the North Wales, &c., district, makes the following interesting allusion to this disease: "When I learnt that the company owning the Frongoch mine in Cardiganshire had imported a number of Italian workmen it occurred to me that they might unwittingly be the means of introducing ankylostomiasis, or miners' anæmia, into this country. I at once put myself into communication with the mine doctor, who reported to me that certain of the men were unwell, and possibly suffering from this disease. I obtained samples of their evacuations, and with your permission transmitted them to Dr. Malvoz, of the Bacteriological Institute, Liége, who has had much experience in searching for the obnoxious parasite among miners in his own country. I was glad to learn from him that, after careful investigations, he had come to the conclusion that the men were free from the disease. Though there is little chance of the eggs being hatched and the disease being propagated in the comparatively cold workings of Frongoch it is quite possible that infested foreign workmen may go into other mines which afford such conditions of warmth and dampness as are necessary for hatching the larvæ. Here there would be danger and seeing the havoc which the malady has caused among miners on the Continent it is well for the British employer to be on his guard. For my own part I would not employ a foreign workman below ground in a warm and damp mine until I had satisfied myself by a simple microscopical examination that he was free from the troublesome worm. It is in no spirit of hostility to Italian workmen that I make this remark. I lived among them for three years and know from experience that many of them are hard-working and excellent miners; it is, moreover, to their own advantage to be freed from the troublesome intruder and there is no reason why they should not be employed at the surface until the mine owner has satisfied himself that they are clear of it." The importance of the ankylostomum duodenale is very great for the anæmia to which it gives rise is extremely severe and often fatal. In countries in which it is endemic a very large proportion of the inhabitants are affected, and Dobson found it in India in the stools of 75 per cent of persons to whom he had administered thymol and it is said to be discovered in the intestine at nearly every post-mortem examination in Egypt. The disease, according to Cobbold, is not endemic in this country and therefore every effort should be made to exclude it. Fortunately we have in thymol, if properly administered, a very efficient means of treatment, though it must not be given with any liquid which will dissolve it, for otherwise severe symptoms of poisoning occur.

FEVER IN SYPHILIS.

IN syphilis fever of such degree as to attract attention seldom occurs, but the subject is well worthy of investigation. The *New York Medical Journal* of June 22nd contains an important paper by Dr. Thomas B. Futcher, which includes descriptions of three cases from the clinic of Professor Osler in the Johns Hopkins Hospital. Syphilitic fever may occur—very rarely—three or four weeks before the secondary eruption. It may precede or concur with the secondary eruption. This is the so-called "fever of invasion" and is a common and important symptom of secondary syphilis. Finally, fever may occur at any time during the secondary or tertiary stages. The "fever of invasion" is rarely absent at the onset of the secondary symptoms. It usually precedes the eruption by a week or 10 days and is accompanied by headache, malaise, and general pains. It may be moderate, not reaching 101° F., or the afternoon elevation may be as high as 104° or 105°. The pyrexia may be of a continuous, remittent, or intermittent type. Case 1.—A married woman, aged 34 years, was admitted to hospital on Sept. 28th, 1900, complaining of abdominal pain which had begun three weeks before. On the previous night she had a rigor which was followed by sweating. On Sept. 29th and 30th the temperature ranged between 98·7° and 101° F. On Oct. 1st a pelvic abscess, which possibly was the cause of the fever, was evacuated per vaginam. The temperature failed to fall and on Oct. 4th, after a rigor and profuse sweating. it rose to 104·2°. There was slight erythema. One of the acute exanthemata was thought to be developing. The temperature fell slowly and had not reached normal before another febrile exacerbation occurred (on Oct. 6th), 105·5° being reached. It fell rapidly and reached normal on Oct. 7th A third exacerbation took place on the 9th and a fourth on the 14th. From this time the temperature gradually fell, but there were slight evening elevations. No cause for the pyrexia could be found in the pelvis or elsewhere. The character of the fever suggested æstivo-autumnal malarial infection, but repeated examinations of the blood failed to show parasites. The spleen was palpable, but Widal's reaction was negative. As the temperature was elevated only about 1° every day the patient was discharged practically well on Oct. 21st. She returned on the 30th with a macular and papular syphilitic eruption. Inquiry showed that her husband had been under treatment for a chancre on August 11th and that he had a syphilitic eruption on August 27th. No history of primary sore in the patient could be obtained. It is noteworthy that the eruption did not appear until practically four weeks after the onset of fever and when the temperature had subsided to normal for some time (A similar case was recorded by Dr. Burney Yeo in the *British Medical Journal* in 1884 (vol. i., p 317) The patient had fever ranging as high as 104° or 105° F., with daily oscillations of 5° or 6°, which began from 25 to 30 days after exposure and from three to four weeks before the appearance of the secondary eruption.) Case 2—A man, aged 39 years, was admitted to hospital on August 8th, 1894, complaining of pains all over the body. For three weeks he had felt feverish and had been unable to work. For a week he had had nausea, vomiting, and diarrhœa. The spleen was felt four centimetres below the ribs. Examination for malarial parasites was negative. The temperature at 8 P.M. was 103·4° F.; it ran a remittent or intermittent course, being 102° or 103° in the evenings. Typhoid fever was prevalent and the case was treated as such. On Sept. 12th it was noticed that both clavicles towards their sternal ends were remarkably thickened and bowed. The patient said that he had had a sore on the prepuce. Iodide of potassium was given in 15-grain doses thrice daily and the dose was gradually increased. The effect was striking. From Sept. 13th the temperature gradually fell. On the 16th it became normal and so remained The patient was discharged on Oct. 18th feeling well. Case 3—An unmarried man, aged 57 years, was admitted to hospital on August 24th, 1892, complaining of chills and fever. He contracted syphilis in 1864 and had a number of tertiary ulcers On June 15th, 1892, several sores appeared on the body. About the end of July recurring chills with temperatures of from 102° to 104° F. began. They were thought to be malarial but did not yield to quinine. Two weeks before admission tenderness and swelling developed over the sternum and in the left shoulder-joint Iodide of potassium was given. On admission the chills had ceased, but there were evening elevations of temperature to 101°. Under the iodide the temperature gradually became normal Syphilitic fever is thus liable to be mistaken for a number of conditions—malarial, typhoid, and other acute fevers, tuberculosis, and acute rheumatism. Hence in all obscure cases of fever syphilis should be looked for.

ARGYLL-ROBERTSON PUPILS AS AN EARLY SIGN OF SYPHILITIC DISEASE OF THE NERVOUS SYSTEM.

AT the meeting of the Société Médicale des Hôpitaux of Paris on May 17th M. G Babinski and M. Charpentier communicated an important paper on this subject. In a previous publication they endeavoured to establish that permanent abolition of the pupillary reflexes, particularly of the light reflex, is a sign almost, if not completely, pathognomonic of acquired or inherited syphilis [1] They presented four patients illustrating this view. Case 1.—A woman, aged 34 years, had acquired syphilis at the age of 27 years She had nodes and Argyll-Robertson pupils. There were no signs of organic nervous disease, the tendon reflexes were normal, sight was good, micturition was normal, Romberg's sign was absent, and there had never been any pains Case 2.—A woman, aged 48 years, contracted syphilis at the age of 16 years. The pupils responded to accommodation but not to light. There was no other sign of nervous disease Case 3.—A man, aged 46 years, contracted syphilis at the age of 31 years. Argyll-Robertson pupils were the only sign of nervous disease present, but, contrary to the preceding cases, the patient had suffered for several months from lancinating pain and his memory was becoming enfeebled. Case 4.—A woman, aged 52 years, had Argyll-Robertson pupils. There was no other sign of nervous disease or history of syphilis, but she had had one abortion. Since infancy she had had "sabre-shaped tibiæ." Hereditary syphilis was thought probably to be present. M. Babinski and M. Charpentier think that the abolition of the pupillary reflex in such cases is a sign that the central nervous system has been attacked by syphilis and that the patient is "a candidate for locomotor ataxy, general paralysis, or confirmed cerebro-spinal syphilis." The interval between the appearance of the sign and the development of other signs of these diseases may be very brief or may be prolonged indefinitely. There are cases intermediate between the types of these diseases in their completely developed form and those cases in which abolition of the pupillary reflex is the sole sign of nervous disease Case 3 is an example. As Argyll-Robertson pupils, which are of such high value in the diagnosis of early syphilis of the nervous system, may be present without loss of vision they are not likely to attract the attention of the patient Hence they should be looked for systematically by the practitioner. Their recognition is of great importance They reveal the existence of a state which is often the precursor of grave troubles and imperatively demands specific treatment. This early stage is the most favourable time for the treatment of syphilitic nervous disease.

TREATMENT OF INSOMNIA AND DELIRIUM DUE TO COMBINED ALCOHOLISM AND NICOTINISM.

A REMARKABLE case of insomnia and delirium due to combined alcoholism and nicotinism is recorded by Dr. John E Beebe of Chicago in the *Journal of Nervous and Mental Diseases* for June, together with the results of treatment. The case was that of a man, aged 34 years, married, and of good family He had been placed in a sanatorium to undergo treatment for the abuse of whisky and cigarettes. The result of enforced abstinence was that he quickly passed from a state of relatively good health into a condition of furious delirium, difficult to control, and attended by marked insomnia; for two weeks he had been under continual supervision, and he was at length showing symptoms of cerebral exhaustion. His history was that he had smoked on an average from 40 to 80 cigarettes per diem since he was 18 years of age "During the six weeks he was under my care," says Dr. Beebe, "a steady pitch-like flow of disagreeable odour oozed from his nicotine-stained hands" The young man, a son of luxury, had been drinking excessively for over six years, and his digestive and intestinal functions were considerably disordered and impaired. A diagnosis of alcoholic delirium, complicated with profound nicotinism, was made. The chief difficulty was to induce rest and quiet in the patient who was delirious, restless, roaming about his room, and gibbering without being still even for a few minutes. Morphine was given both hypodermically and by the mouth but without effect The bromides were likewise ineffective, and chloral seemed only to add to the frenzy of the already exhausted patient. Having obtained a slight relief with trional it was now determined to push this drug. Doses of from 10 to 30 grains were given at first, but after a few trials 15 grains every four hours and up to 90 grains per diem were given. At first his restlessness and delirium continued with slight remissions, the culminating point of his disorder being reached once when he lay restless and sleepless for 36 hours, in spite of everything that could be done. At this stage the patient was treated with hot-water packs, the hottest that he could endure, and held firmly in bed, while during 24 hours he was treated with trional to the total extent of 117 grains. After this he went to sleep for about 20 hours. Henceforth from time to time he was given large doses of the same drug, while the strongest stimulants were given hypodermically to keep his failing heart up to its work, especially as the patient had suffered for over a year from a weak heart which at one time caused much anxiety when he was undergoing a surgical operation a year previously. After a period of six weeks of the above treatment he recovered, his body-weight, however, showing a loss of about 30 pounds. The temperature during the earlier half of the period varied from 101° to 103° F. No single bad effect was observed from the large doses of trional with which he was treated, the aggregate quantity administered up to the beginning of convalescence being several ounces. From the above and a number of other cases Dr. Beebe concludes that "if attention is paid to elimination, if liquid foods are freely and regularly used, and if the heart is kept in the best possible condition," trional will prove successful in the treatment of such cases as the above.

[1] Bulletin de la Société de Dermatologie, June 13th, 1899.

IS ICE INNOCENT?

ALLEGATIONS have from time to time been made against ice as a possible source of infection, and in 1893 we instituted a practical inquiry upon the subject so far as it related to the London ice-supply. The results on the whole were of a reassuring character in the light both of chemical and bacteriological examination. It was shown that certainly not less than nine-tenths of the ice sold in London were obtained from small lakes and ponds in Norway, situated in such solitary and secluded sites as to render any contamination with animal matters highly improbable. According to a fresh inquiry commenced last week, we still find that most of the ice supplied in London shops is Norwegian ice and, moreover, that it is of excellent quality, pure, sparkling, and clean. There might, of course, be exceptions to this. The water which was yielded on melting contained less than a grain per gallon of dissolved mineral matter, no nitrogen either in organic or mineral shape, and but a trace of chlorides. In short, the composition of the ice-water approached very nearly to that of distilled water or of the water of mountain streams. It was very soft and very pure. There were a few ordinary and harmless species of water bacteria present. These results are excellent and show that the Norwegian ice-supply is highly satisfactory and that no harm is likely to accrue even when the ice is consumed as it is when placed in beverages for cooling purposes. One curious fact came to light during our experiments and that was that if the ice be allowed to melt in a leaden vessel the resulting water was found to contain a very appreciable amount of the poisonous metal. This is not surprising when we consider how very soft Norwegian ice-water is, but it affords the important lesson that care should be taken not to keep melting ice in leaden vessels or to allow it to come into contact with lead in any way.

THE SUSPECTED CASES OF PLAGUE AT PLYMOUTH.

THE circumstances connected with the arrival of the *Ormuz* at Marseilles were sufficient to raise a suspicion that there had been, or were, cases of plague on board. The *Ormuz* left Sydney on June 8th and touched on her homeward journey at the usual ports of call. She carried a crew of 160 Europeans and 174 passengers. It appears that on July 5th a coal-trimmer who had shipped at Sydney developed inguinal buboes and certain other symptoms suspicious of bubonic plague, and on July 17th another of the crew noticed an axillary swelling, which, however, may have had as its cause a burn on the finger. Both cases were, it seems, regarded with suspicion, and as the restrictions sought to be imposed upon the *Ormuz* at Marseilles were somewhat onerous, the captain elected to forthwith proceed to sea. Both patients have now, we understand, been isolated in the port sanitary hospital at Plymouth, and, although the local bacteriologist has had some suspicions as to the real nature of the disease, it is not improbable that the cases may eventually be regarded in a negative light. However this may be, the patients are comfortably housed, or rather shipped, in Plymouth Sound, and are not likely to be the means of infecting the town itself.

THE Royal Commissioners appointed in 1898 to inquire into and to report as to what methods of treating and disposing of sewage may properly be adopted have issued a preliminary document in which they deal with some of the more urgent questions on the subject. With certain reservations they doubt if any land is entirely useless for the purpose. They are satisfied that satisfactory effluents can be produced by bacteriological methods in many instances without interposing land treatment. They suggest the creation of a new department of the Local Government Board—"a supreme rivers authority"—to deal with the pollution and purification of rivers and to keep local authorities up to a strict sense of their duty in these matters.

THE deaths are announced of two noteworthy medical men. The name of Mr. Carsten Holthouse, who died in his ninety-first year, stood first on the chronological list of the Fellows of the Royal College of Surgeons of England. Dr. E. S. Morley was a prominent practitioner in Blackburn and was an elder brother of the Right Hon. John Morley, M.P. We hope to publish obituary notices of both these gentlemen in a future issue.

A DINNER was given in honour of Professor Robert Koch, M.D., by the Royal Institute of Public Health at the Hôtel Métropole on July 24th. The Harben Gold Medal and the Honorary Fellowship of the institution were presented to Professor Koch in recognition of his many notable scientific researches.

MR. MALCOLM MORRIS will deliver the Lane Lectures at San Francisco in the first week in September on the subject of Skin Diseases.

COUNTY OF DURHAM MEDICAL UNION.

THE third annual meeting of this union was held in the Mayor's Chamber at the Town Hall, Durham, on June 28th, Alderman E. JEPSON, M.D. Durh., the President, being in the chair. There was a large attendance of members from Durham, South Shields, Whickham, Jarrow, Low Fell, Gateshead, Bishop Auckland, Sunderland, West Hartlepool, Stockton-on-Tees, Wingate, Stanley, Howden-le-Wear, Sedgefield, Willington, Ryton-on-Tyne, Washington, Sherburn, Easington, and Spennymoor.

The PRESIDENT, in opening the meeting, congratulated the members on this being the third annual meeting. He said that some had predicted an early decline for their union, but rather than decline or signs of decay there were indications and evidences of more stability. It was true that they were not engaged in any sharp conflict at that time, but the union had gradually asserted itself in many places and a higher rate of pay had become recognised in many parts of the county. The position of those directly opposed to the union was becoming worse every day. The President further stated that he and Dr. Alfred Cox (Gateshead) had been invited to a meeting of the Hartlepool Medical Society to explain to the members of that society the objects and aims of the union with a view to their affiliation with them, and that they attended and so far pleaded their case that two days since he had received a letter from Dr. H. Schmitz, the secretary of the Hartlepool Medical Society, to say that that society had unanimously resolved to become affiliated to the union. This, he considered, was very gratifying, and pointed distinctly to growth and strength in the union. He added that he had repeatedly tried to induce the Darlington Medical Society to become affiliated with them, but hitherto without success That day, however, he had had a letter from Dr. J. Hern to say that the matter would be further considered in October. There was one more society to be wooed and won, and that was the Gateshead Medical Association. When these two societies had joined them the county union would be nearly complete. In conclusion, he thanked them for their kindness and courtesy during the past year, and begged them most earnestly to use a free and open mind in performing the duty of electing his successor.

Dr. J. F. ARMSTRONG (South Shields) said that he had very great pleasure in moving the re-election as President of Dr. Jepson who had been a great power and help to the society. He had spared neither time nor trouble in furthering their interests.

Mr. W. GALLOWAY (Low Fell) seconded the motion which was carried unanimously.

The PRESIDENT, in returning thanks, said that he did not believe in repeated re-elections, but he could not resist their kindness and would do all in his power to help on the union.

On the motion of Mr. M. A. WARDLE (Bishop Auckland) and Mr. A. W. Attwater (Whickham), Dr. James Murphy (Sunderland) was unanimously re-elected Vice-President.

The following were elected members of the Council: Dr. Armstrong (South Shields), Dr. Cox (Gateshead), Mr. Galloway (Low Fell), Dr. J. H. Hunter (South Shields), Dr. R. S. Hubbersty (Sunderland), Mr. R. E. Ingram-Johnson (South Moor), Dr. C. F. G. Mann (Washington), Dr. G. V. Miller (Stockton), Dr. A. Mackay (Crook), Dr. J. Taylor (Chester-le-Street), Mr. R. Stuart (Durham), Mr. Wardle (Bishop Auckland), Mr. E. S. Davis (Hartlepool), Mr. Arthur (Wingate), Dr. G Stephen (West Auckland), Mr. K. C. Hill (Jarrow), Dr. J. Charles (Stanley), Mr. Attwater (Whickham), [illegible] A. D. M. McIntyre (Bl[illegible] A. A. D. Parker (Easin[illegible] H. Lyon Smith who is [illegible] he place of Mr. W. Ni[illegible] practice, and Mr. Arthur takes the place of Dr. W. A. G. Russell who was, it was stated, at the seat of war in South Africa. Messrs. Graham and Shepherd (Sunderland) were re-elected joint secretaries, treasurers, and solicitors. Dr. C. D. Hill Drury (Darlington), Dr. Hern (Darlington), Dr. David V. McIntyre (Brandon), and Mr. Davis (Hartlepool) were elected members.

The treasurers' statement, showing a balance of £66 3*s*. 1*d*. in favour of the union, was submitted and adopted. A sum of £50 was ordered to be paid to the secretaries on account of the balance due to them. Reports were made by representatives from Sunderland, Chester-le-Street, Stanley, Jarrow and Hebburn, Consett, Trimdon, and Stockton, which were generally very satisfactory.

Some discussion took place as to the fixing of a minimum midwifery fee for the county, and Mr. ATTWATER (Whickham) gave notice that at the next meeting he would bring forward a motion fixing the minimum midwifery fee at 15*s*.

Mr. ATTWATER moved :—

> That in [illegible] of the great [illegible]

Several members expressed themselves in favour of the desirability of such an agency being attached to the union, and the motion was carried unanimously.

Mr. SHEPHERD, on behalf of his firm, promised to give the matter careful consideration. He thought an agency of the kind would be a most useful adjunct to the union

The SECRETARIES reported that the resolution unanimously passed at the general meeting on Feb. 5th requesting the General Medical Council to remove from the Register any medical practitioner who countenanced or encouraged canvassing by any union or association of working men and others on his behalf had been brought before the Executive Committee of the General Medical Council on June 3rd, but that no action was taken thereon. Great disappointment was expressed at the lack of interest in matters affecting the general practitioner thus displayed by the General Medical Council, and it was unanimously resolved, on the motion of Mr. ATTWATER, seconded by the VICE-PRESIDENT, and supported by Dr. ARMSTRONG, Dr. CHARLES, and Mr. ARTHUR, that the resolution should be again sent to the General Medical Council and that Mr. G. Brown, Mr. Victor Horsley, and Dr. J G. Glover should be specially asked to give it their support.

A reprint of the rules with the amendments made since the first issue was ordered; and on the motion of the PRESIDENT, seconded by Dr. ARMSTRONG, it was agreed that a half-yearly letter or report should be sent out in the months of March and October to all the members, giving a short statement as to the work which had been done and of the meetings held, and as to any resolutions, &c., passed, so as to keep the members in touch with the executive.

Considerable interest was evinced in the question of the fees paid by insurance companies for medical examinations and it was decided that the matter should be further considered at the next meeting. The PRESIDENT said that he would give notice of a proposition which he would move on the subject.

A hearty vote of thanks to the President brought a successful meeting to a close.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6377 births and 3927 deaths were registered during the week ending July 20th. The annual rate of mortality in these towns, which had been 15·1 and 15·6 per 1000 in the two preceding weeks, further rose to 17·9 per 1000 last week. In London the death-rate *was 16·2, while it averaged 19·0 in the 32 large provincial* towns. The lowest death-rates in these towns were 7·7 in Croydon, 8·4 in Brighton, 11·9 in Hull, and 12·0 in Cardiff; the highest rates were 22·5 in Blackburn, 29·1 in Birkenhead and in Sheffield, and 30·5 in Liverpool. The 3927 deaths in these towns last week included 897 which were referred to the principal zymotic diseases, against 431 and 567 in the two preceding weeks; of these, 616 resulted from diarrhœal diseases, 103 from measles, 62 from diphtheria, 49 from whooping-cough, 35 from "fever" (principally enteric), 32 from scarlet fever, and not one from small-pox. No death from any of these diseases was registered last week in Brighton; in the other towns they caused the lowest death-rates in Croydon, Wolverhampton, and Hull, and the highest in Birkenhead, Liverpool, and Sheffield. The greatest mortality from measles occurred in Leeds and Birkenhead; from scarlet fever in Blackburn; from whooping-cough in Newcastle and Swansea; and from diarrhœa in Preston, Leeds, Birkenhead, Sheffield, and Liverpool. The mortality from "fever" showed no marked excess in any of the large towns The 62 deaths from diphtheria in the 33 towns included 30 in London, five in Leicester, five in Manchester, five in Salford, and four in West Ham. No fatal case of small-pox was registered in any of the 33 towns; five small-pox patients were admitted into the Metropolitan Asylums hospitals during the week, and 14 remained under treatment on Saturday, July 20th. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2907, against numbers increasing from 1622 to 2918 on the 12 preceding Saturdays; 371 new cases were admitted during the week, against 408, 363, and 324 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 165 and 133 in the two preceding weeks, rose last week to 135, but were 35 below the corrected average The causes of 49, or 1·2 per cent., of the deaths in the 33 towns were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Salford, Bradford, Cardiff, Sunderland, and Oldham, and in 10 other smaller towns; the largest proportions of uncertified deaths were registered in Leeds, Sheffield, Birmingham, and Liverpool.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·0 and 17·2 per 1000 in the two preceding weeks, rose again to 18·4 per 1000 during

during 24 hours he was treated with trional to the total extent of 117 grains. After this he went to sleep for about 20 hours. Henceforth from time to time he was given large doses of the same drug, while the strongest stimulants were given hypodermically to keep his failing heart up to its work, especially as the patient had suffered for over a year from a weak heart which at one time caused much anxiety when he was undergoing a surgical operation a year previously. After a period of six weeks of the above treatment he recovered, his body-weight, however, showing a loss of about 30 pounds. The temperature during the earlier half of the period varied from 101° to 103° F. No single bad effect was observed from the large doses of trional with which he was treated, the aggregate quantity administered up to the beginning of convalescence being several ounces. From the above and a number of other cases Dr. Beebe concludes that "if attention is paid to elimination, if liquid foods are freely and regularly used, and if the heart is kept in the best possible condition," trional will prove successful in the treatment of such cases as the above.

IS ICE INNOCENT?

ALLEGATIONS have from time to time been made against ice as a possible source of infection, and in 1893 we instituted a practical inquiry upon the subject so far as it related to the London ice-supply. The results on the whole were of a reassuring character in the light both of chemical and bacteriological examination. It was shown that certainly not less than nine-tenths of the ice sold in London were obtained from small lakes and ponds in Norway, situated in such solitary and secluded sites as to render any contamination with animal matters highly improbable. COUNTY OF DURHAM MEDICAL UNION.

THE third annual meeting of this union was held in the Mayor's Chamber at the Town Hall, Durham, on June 28th, Alderman E. JEPSON, M.D. Durh., the President, being in the chair. There was a large attendance of members from Durham, South Shields, Whickham, Jarrow, Low Fell, Gateshead, Bishop Auckland, Sunderland, West Hartlepool, Stockton-on-Tees, Wingate, Stanley, Howden-le-Wear, Sedgefield, Willington, Ryton-on-Tyne, Washington, Sherburn, Easington, and Spennymoor.

The PRESIDENT, in opening the meeting, congratulated the members on this being the third annual meeting. He said that some had predicted an early decline for their union, but rather than decline or signs of decay there were indications and evidences of more stability. It was true that they were not engaged in any sharp conflict at that time, but the union had gradually asserted itself in many places and a higher rate of pay had become recognised in many parts of the county. The position of those directly opposed to the union was becoming worse every day. The President further stated that he and Dr. Alfred Cox (Gateshead) had been invited to a meeting of the Hartlepool Medical Society to explain to the members of that society the objects and aims of the union with a view to their affiliation with them, and that they attended and so far pleaded their case that two days since he had received a letter from Dr. H. Schmitz, the secretary of the Hartlepool Medical Society, to say that that society had unanimously resolved to become affiliated to the union. This, he considered, was very gratifying, and pointed distinctly to growth and strength in the union. He added that he had repeatedly tried to induce the Darlington Medical Society to become affiliated with them, but hitherto without success. That day, however, he had had a letter from Dr. J. Hern to say that the matter would be further considered in October. There was one more society to be wooed and won, and that was the Gateshead Medical Association. When these two societies had joined them the county union would be nearly complete. In conclusion, he thanked them for their kindness and courtesy during the past year, and begged them most earnestly to use a free and open mind in performing the duty of electing his successor.

Dr. J. F. ARMSTRONG (South Shields) said that he had very great pleasure in moving the re-election as President of Dr. Jepson who had been a great power and help to the society. He had spared neither time nor trouble in furthering their interests.

Mr. W. GALLOWAY (Low Fell) seconded the motion which was carried unanimously.

The PRESIDENT, in returning thanks, said that he did not believe in repeated re-elections, but he could not resist their kindness and would do all in his power to help on the union.

On the motion of Mr. M. A. WARDLE (Bishop Auckland) and Mr. A. W. Attwater (Whickham), Dr. James Murphy (Sunderland) was unanimously re-elected Vice-President.

The following were elected members of the Council: Dr. Armstrong (South Shields), Dr. Cox (Gateshead), Mr. Galloway (Low Fell), Dr. J. H. Hunter (South Shields), Dr. R. S. Hubbersty (Sunderland), Mr. R. E. Ingram-Johnson (South Moor), Dr. C. F. G. Mann (Washington), Dr. G. V. Miller (Stockton), Dr. A. Mackay (Crook), Dr. J. Taylor (Chester-le-Street), Mr. R. Stuart (Durham), Mr. Wardle (Bishop Auckland), Mr. E. S Davis (Hartlepool), Mr. Arthur (Wingate), Dr. G. Stephen (West Auckland), Mr. K. C. Hill (Jarrow), Dr. J. Charles (Stanley), Mr. Attwater (Whickham), Dr. R. S. Anderson (Spennymoor), Dr. A. D. M. McIntyre (Blackhill), Dr. D. Wilson (Birtley), Mr. A. A. D. Parker (Easington). Dr. Taylor takes the place of Mr. H. Lyon Smith who is leaving the district, Mr. Davis takes the place of Mr. W. Nisbet (Thornley) who has retired from practice, and Mr. Arthur takes the place of Dr. W. A. G. Russell who was, it was stated, at the seat of war in South Africa. Messrs. Graham and Shepherd [illegible] ed joint secretaries, treasurers, a[illegible] ill Drury (Darlington), Dr. Hern (Darlington), Dr. David V. McIntyre (Brandon), and Mr. Davis (Hartlepool) were elected members.

The treasurers' statement, showing a balance of £66 3*s.* 1*d.* in favour of the union, was submitted and adopted. A sum of £50 was ordered to be paid to the secretaries on account of the balance due to them. Reports were made by representatives from Sunderland, Chester-le-Street, Stanley, Jarrow and Hebburn, Consett, Trimdon, and Stockton, which were generally very satisfactory.

Some discussion took place as to the fixing of a minimum midwifery fee for the county, and Mr. ATTWATER (Whickham) gave notice that at the next meeting he would bring forward a motion fixing the minimum midwifery fee at 15*s.*

Mr. ATTWATER moved :—

Several members expressed themselves in favour of the desirability of such an agency being attached to the union, and the motion was carried unanimously.

Mr. SHEPHERD, on behalf of his firm, promised to give the matter careful consideration. He thought an agency of the kind would be a most useful adjunct to the union

The SECRETARIES reported that the resolution unanimously passed at the general meeting on Feb 5th requesting the General Medical Council to remove from the Register any medical practitioner who countenanced or encouraged canvassing by any union or association of working men and others on his behalf had been brought before the Executive Committee of the General Medical Council on June 3rd, but that no action was taken thereon. Great disappointment was expressed at the lack of interest in matters affecting the general practitioner thus displayed by the General Medical Council, and it was unanimously resolved, on the motion of Mr. ATTWATER, seconded by the VICE-PRESIDENT, and supported by Dr. ARMSTRONG, Dr. CHARLES, and Mr. ARTHUR, that the resolution should be again sent to the General Medical Council and that Mr. G. Brown, Mr. Victor Horsley, and Dr. J. G. Glover should be specially asked to give it their support.

A reprint of the rules with the amendments made since the first issue was ordered; and on the motion of the PRESIDENT, seconded by Dr. ARMSTRONG, it was agreed that a half-yearly letter or report should be sent out in the months of March and October to all the members, giving a short statement as to the work which had been done and of the meetings held, and as to any resolutions, &c., passed, so as to keep the members in touch with the executive.

Considerable interest was evinced in the question of the fees paid by insurance companies for medical examinations and it was decided that the matter should be further considered at the next meeting. The PRESIDENT said that he would give notice of a proposition which he would move on the subject.

A hearty vote of thanks to the President brought a successful meeting to a close.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6377 births and 3927 deaths were registered during the week ending July 20th. The annual rate of mortality in these towns, which had been 15·1 and 15·6 per 1000 in the two preceding weeks, further rose to 17·9 per 1000 last week. In London the death-rate was 16·2, while it averaged 19·0 in the 32 large provincial towns. The lowest death-rates in these towns were 7·7 in Croydon, 8·4 in Brighton, 11·9 in Hull, and 12·0 in Cardiff; the highest rates were 22·5 in Blackburn, 29·1 in Birkenhead and in Sheffield, and 30·5 in Liverpool. The 3927 deaths in these towns last week included 897 which were referred to the principal zymotic diseases, against 431 and 567 in the two preceding weeks; of these, 616 resulted from diarrhœal diseases, 103 from measles, 62 from diphtheria, 49 from whooping-cough, 35 from "fever" (principally enteric), 32 from scarlet fever, and not one from small-pox. No death from any of these diseases was registered last week in Brighton; in the other towns they caused the lowest death-rates in Croydon, Wolverhampton, and Hull, and the highest in Birkenhead, Liverpool, and Sheffield. The greatest mortality from measles occurred in Leeds and Birkenhead; from scarlet fever in Blackburn; from whooping-cough in Newcastle and Swansea; and from diarrhœa in Preston, Leeds, Birkenhead, Sheffield, and Liverpool. The mortality from "fever" showed no marked excess in any of the large towns The 62 deaths from diphtheria in the 33 towns included 30 in London, five in Leicester, five in Manchester, five in Salford, and four in West Ham. No fatal case of small-pox was registered in any of the 33 towns; five small-pox patients were admitted into the Metropolitan Asylums hospitals during the week, and 14 remained under treatment on Saturday, July 20th. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2907, against numbers increasing from 1522 to 2918 on the 12 preceding Saturdays; 371 new cases were admitted during the week, against 408, 363, and 324 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 165 and 133 in the two preceding weeks, rose last week to 135, but were 35 below the corrected average. The causes of 49, or 1·2 per cent., of the deaths in the 33 towns were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Salford, Bradford, Cardiff, Sunderland, and Oldham, and in 10 other smaller towns; the largest proportions of uncertified deaths were registered in Leeds, Sheffield, Birmingham, and Liverpool

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·0 and 17·2 per 1000 in the two preceding weeks, rose again to 18·4 per 1000 during the week ending July 20th, and was 0·5 per 1000 above the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 14·2 in Perth and 14·8 in Aberdeen to 19·1 in Edinburgh and 22·6 in Dundee. The 585 deaths in these towns included 45 which were referred to diarrhœa, 25 to whooping-cough, 24 to measles, four to scarlet fever, and three to "fever." In all, 101 deaths resulted from these principal zymotic diseases last week, against 81 and 89 in the two preceding weeks. These 101 deaths were equal to an annual rate of 3·2 per 1000, which was 0·9 per 1000 below the zymotic death-rate last week in the 33 large English towns. The fatal cases of diarrhœa, which had been 24, 19, and 29 in the three preceding weeks, further rose last week to 45, and included 26 in Glasgow, six in Edinburgh, five in Dundee, four in Aberdeen, and three in Paisley. The deaths from measles, which had been 25, 25, and 22 in the three preceding weeks, rose last week to 24, of which 17 occurred in Glasgow and six in Dundee. The fatal cases of whooping-cough, which had declined from 30 to 25 and 22 in the three preceding weeks, rose again last week to 25, and included 11 in Glasgow, 10 in Edinburgh, and three in Dundee. The deaths from scarlet fever, which had been seven in each of the two preceding weeks, fell last week to four, all of which were registered in Glasgow. The deaths from "fever," which had been one and six in the two preceding weeks, fell last week to three, which were all registered in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 95 and 75 in the two preceding weeks, rose last week to 79, but were one below the number in the corresponding period of last year. The causes of 23, or more than 4 per cent., of the deaths in these towns last week were not certified.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been 20·7 and 21·0 per 1000 in the two preceding weeks, declined again to 18·4 during the week ending July 20th. During the past four weeks the death-rate has averaged 19·6, the rates during the same period being 14·7 in London and 17·1 in Edinburgh. The 132 deaths of persons belonging to Dublin registered during the week under notice were 19 fewer than the number in the preceding week, and included 18 which were referred to the principal zymotic diseases, against seven and 10 in the two preceding weeks; of these 14 resulted from diarrhœa, two from fever, one from diphtheria, and one from scarlet fever. These 18 deaths were equal to an annual rate of 2·5 per 1000, the zymotic death-rate during the same period being 2·9 in London and 2·8 in Edinburgh. The deaths from diarrhœa showed a considerable excess over the numbers recorded in recent weeks. The 132 deaths in Dublin last week included 24 of infants under one year of age and 33 of persons aged upwards of 60 years; the deaths of infants were about equal to the average in recent weeks, and those of elderly persons were rather below the average. Ten inquests were held and seven deaths from violence were registered; and 48, or more than one-third, of the deaths occurred in public institutions. The causes of four, or more than 3 per cent., of the deaths in Dublin last week were not certified.

THE SERVICES.

Royal Army Medical Corps.

Major J. J. P. Doyle has arrived at Brighton for duty and taken over medical charge of the Station Hospital, vice Lieutenant-Colonel J. J. Crean, A.M.S. Lieutenant Adderley is transferred from the Poona District to the Bombay District. Major John Osburne to be Surgeon-Lieutenant. Dated July 20th, 1901.

Army Medical Reserve of Officers.

Surgeon-Lieutenant Leonard Leighton Hanham, 2nd Devonshire Volunteer Artillery, to be Surgeon-Lieutenant. Dated July 20th, 1901.

Volunteer Corps.

Artillery: 7th Lancashire (the Manchester Artillery): Surgeon-Major R. A. S. Daly to be Surgeon-Lieutenant-Colonel. Dated July 20th, 1901. *Rifle:* 1st Cadet Battalion the Royal Fusiliers (City of London Regiment): Arthur Robert Owst to be Surgeon-Lieutenant. Dated July 3rd, 1901. 1st Volunteer Battalion the Lincolnshire Regiment: Surgeon-Captain G. M. Lowe to be Surgeon-Major. Dated July 20th, 1901. 3rd Volunteer Battalion the Royal Welsh Fusiliers: Second Lieutenant John Robert Williams resigns his commission, and is appointed Surgeon-Lieutenant. Dated July 20th, 1901. 1st (Pembrokeshire) Volunteer Battalion the Welsh Regiment: David Arthur Hughes to be Surgeon-Lieutenant. Dated July 20th, 1901. 6th Volunteer Battalion the Gordon Highlanders: Surgeon-Lieutenant T. A. Sellar to be Surgeon-Captain. Dated July 20th, 1901.

South African War Notes.

The following have been discharged from hospital for duty:—*Civil Surgeons:* John Brodie Boyd and Hamilton Arthur Stewart. The following are on passage home: Civil Surgeons: J. Sowden and J. W. Miller.

Affairs in South Africa.

A great deal has taken, and is taking, place since we last chronicled the course of events in South Africa, some of which has an important prospective bearing on the war, while much is of more or less medical interest. The capture and publication of the Reitz-Steyn correspondence come under the first category. It discloses a disorganised state of things in regard to the Boers and their Governments which has been long suspected and it serves to demonstrate the necessity of a vigorous prosecution of our military policy by mounted troops if we would overcome resistance and put an end to hostilities. While we can all be touched with a feeling of pity in connexion with the circumstances attending the illness and death of Mrs. Kruger at Pretoria, separated by so many miles from her husband, and the grief which her death has naturally caused to Mr. Kruger, this country has nevertheless the satisfaction of feeling that all that kindly consideration and forbearance could do for Mrs. Kruger was done. With regard to the concentration camps the Government have appointed a committee of ladies to inquire into and to report upon the arrangements made by the military and medical authorities. We imagine that this is the first time that such a step has been taken. In addition to the casualties from repelling attacks by the Boers in their various raids, there are still rather long lists of sick from various causes incidental to war and camps. There has been a reception at Marlborough House by the King of a deputation of American ladies to present His Majesty with a memento of the work done by the American hospital ship *Maine* for the sick and wounded in South Africa and China in 1900 and 1901. A gold medal, which had been designed and struck for the purpose of presentation to Her late Majesty Queen Victoria was offered to, and accepted by, the King. The *Maine* was at the end of her work, it will be remembered, presented to the British Government.

Vital Statistics of the German Navy, 1897–1899.

A biennial statistical report on the Imperial German Navy has been issued for the period ending March 31st, 1899. It is a voluminous document, comprising 315 pages, and contains a large amount of valuable and well-arranged matter in addition to numerous tables and diagrams. In the first half of the biennium the average strength, afloat and ashore, was 22,692 men, but during the second twelvemonth it rose to 27,067, an increase of nearly 20 per cent. The general admission-rate, at home and abroad, was 790 per 1000 per annum for the two years, which was about the same as that prevailing among the German land forces. The average time under treatment was 16·5 days per case, and 37 men were constantly sick out of each 1000. The first year the death-rate was 3·5 per 1000, but the second year it fell to 2·8 per 1000, the average for the two years being consequently 3·15 per 1000. This [illegible] compares favourably with that of all the [illegible] statistics, but in gauging its tru[illegible] rates must be taken into account. In 1887–88 the average number of men invalided from the German navy was 14 per 1000, whereas in the first of the two years under report the loss from this cause was 40 per 1000 and in the second 38 per 1000. The revaccinations during the biennium amounted to 19,884, and in no fewer than 12,935 instances, being 65 per cent. of the whole, the operation was successful. Of the failures 5201 were again vaccinated, some for a fourth or fifth time, success attending on 29 per cent. of the attempts. The capital operations performed during the period were

84 in number. Among them there were two trephinings (both successful), four laparotomies (two deaths), four operations for appendicitis (all successful), 13 operations for the radical cure of hernia (all likewise successful). 23 sick-men were sent for treatment to Wiesbaden, Aix, Oyenhausen, and Teplitz, their disabilities being mostly chronic rheumatism, sciatica, and syphilis.

DEATHS IN THE SERVICES.

Surgeon-Major Frederick Robinson, at his residence at Eastbourne on July 21st. He entered the service as Assistant Surgeon in the 74th Foot and was transferred to the Scots Fusilier Guards in 1852. He became Surgeon-Major of the battalion in 1867. He accompanied the Scots Fusilier Guards to the Crimea and served with the battalion until the termination of the war. He was present at the battles of the Alma, Balaclava, and Inkerman and at the siege and fall of Sebastopol and the sortie of Oct. 26th (British medal with four clasps, Medjidieh and Turkish medals). Surgeon-Major Robinson was the author of "A Diary of the Crimean War."

GENERAL BADEN-POWELL'S HOSPITALS.

The generous donors of literature and subscriptions to [illegible] s to the South [illegible] know that the [illegible] ng shipped this week, thus carrying out General Baden-Powell's personal wish expressed in a letter to Lady Sarah Wilson as follows: "My idea was to make up the books into cases of say 50 to 100 volumes in strong, locked travelling cases. A case would be sent to each hospital for a month and then passed on to the next hospital. In this way there would be a monthly arrival of a fresh lot of books."

HONOURS FOR CHINA AND SOUTH AFRICA.

Colonel J. T. B. Bookey, I.M.S., has been appointed a Companion of the Bath for services rendered during the recent operations in China, and the following officers have been appointed to Companionships of the Order of the Indian Empire for services in the same operations: Lieutenant-Colonel W. J. R. Rainsford, R.A.M.C., Major J. J. C. Watson, R.A.M.C., and Lieutenant-Colonel L. A. Waddell, I.M.S.

The King has appointed Deputy Surgeon-General H. J. Blanc to be Knight Commander of the Royal Victorian Order.

Sir William Thomson, C.B., has been appointed a member of the Army Medical Reorganisation Committee.

Correspondence.

"Audi alteram partem."

"THE CONTAMINATION OF POST-OFFICES."

To the Editors of THE LANCET.

SIRS,—A letter in THE LANCET of July 20th, p. 171, under the heading "The Contamination of Post-offices," signed "P. M. O." sets out with the laudable intention of enlightening the public on the very numerous inaccuracies of certain other letters. The latter part of this letter contains some reference to a previous communication from me. "P. M. O." refers to my "allegations as to the excessive prevalence of tubercle among telegraphists" and my "attributing it to the insanitary conditions of post-office buildings." I have looked up my original letter and I find that I referred to "the high incidence of phthisis among certain classes of employés in the English Post Office," those classes being sorting clerks and telegraphists, but I made no comparison with any other class and did not use the word "excessive." The most careful scrutiny of my letter does not reveal the fact that I attributed the phthisical mortality of the Post Office to the insanitation of the buildings or to any other cause. I contented myself with a statement of the facts. The statistics which I quoted were statistics referring to the whole postal ser[illegible] n the annual reports of [illegible] od of calculation I [illegible] Dr. Mignot in calcu[illegible] postal service. Dr. Mignot's report runs as follows:—"During the year 1899, out of nearly 71,000 employés of different grades in the Posts and Telegraphs, 200 were certified as having died from tuberculosis, and 88 were retired on account of the same complaint, making a mortality of 28·1 per 10,000, and a loss from tuberculosis of 40 per 10,000, for it cannot reasonably be supposed that a very large number of those retired escaped death." The total loss is obtained by adding together the deaths and retirements from tuberculous disease. Retirement from the British Post Office on account of phthisis means that the patient's decease from that complaint is assured if not imminent. Applying the same method to the official statistics published by the British Post Office we get the result shown in the following table. The figures refer to the established staff only—every member of which is a selected life:—

Table showing Loss from Phthisis.

Year.	Staff.	Deaths.	Retirements.	Total.	Loss per 1000 living in the postal service.	Loss per 1000 living in the general population.
1896	62,852	86	67	153	2·4	1·3
1897	76,866	72	80	152	1·9	1·3
1898	79,121	70	87	157	1·9	1·3
1899	82,172	62	83	145	1·7	1·3

This table shows that there was a progressive increase in the number of retirements after 1895 and a corresponding decrease in the number of deaths, a fact which proves how close is the relation between the two sets of figures and fully confirms the method of computing the total loss from phthisis.

So much in substantiation of the statistics of my letter. Reference is made by "P. M. O." to other statistics "just issued" which "reveal that this disease exists only to a very limited degree amongst all grades of postal employés." If this statement be true then the Postmaster-General is wrong, for the figures I have quoted are from his annual reports. "P. M. O." must settle this with Lord Londonderry.

But the most extraordinary statement is made that these statistics have been recently collected and apparently classified. "P. M. O.," I imagine, means "Postal Medical Officer," and I also imagine that information in the possession of postal medical officers is readily accessible to the Postmaster-General. Yet on Tuesday, June 18th last, when Sir Walter Foster asked for statistics of this very nature the Postmaster-General's representative replied "that it would be difficult to give all the details referred to," &c.

That the men fall short in many respects in their private life I am ready to admit, and in this matter they share the ignorance of the great mass of the British public concerning the causation and prevention of consumption. But their sanitary standard owes nothing to the intelligence of the Post-office medical department which allows month-old, nay, year-old, dust to remain on the walls of the General Post Office itself, and has provided not a single spittoon nor a publicly exhibited prohibition against expectoration within the buildings.

I am, Sirs, yours faithfully,
CHARLES H. GARLAND.

"UNBOILED v. BOILED MILK."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of July 20th, p. 169, Dr. Robert Hutchison, by producing a large amount of experimental evidence, has completely refuted Dr. Dukes's main contention "that the nutritive value of milk is very largely diminished by boiling." In THE LANCET of August 20th, 1892, p. 434, *are quoted some experiments of* Dr. Chamouin of Paris which support Dr. Hutchison's views. Kittens fed on boiled milk were twice as fat and healthy as those fed on raw milk. Dr. Chamouin also investigated the infantile mortality of Paris and came to the conclusion that "thousands of infants are annually safeguarded from intestinal disease and death by the precaution of boiling the milk on which they feed." It appears to me that Dr. Dukes magnifies the dangers arising from boiled or sterilised milk and minimises those from unboiled milk. One can only form an opinion from one's own experience and mine is decidedly mode adopted for deciding which of the candidates (B and C) should retire is really a fair one. It must be admitted that it was the quickest way of determining the point, but looking at the facts of the situation—viz., that it was well known that the two strongest candidates were A and C and that the supporters of A could easily arrange for some either not to vote at all (as evidently was the case from the fact that there were three papers *unmarked*) or else vote for B, the weaker of the two candidates, it is apparent that although the quickest it was not the *fairest* way of arriving at a decision. It is not probable that there are many examples of such a state of things, but if any of your readers can call to mind any similar ones it would be interesting to know what course was adopted. It would naturally have been a trying process to continue voting for the three candidates until the tie between the second and third ceased to exist. At the same time the interests of the three candidates demanded that some such process should have been adopted. I am, Sirs, yours faithfully,

July, 1901. A GOVERNOR.

THE DEFICIENCY OF CANDIDATES FOR THE MEDICAL SERVICES.

To the Editors of THE LANCET.

SIRS,—Amongst the various reasons accounting for the small number of candidates for the services I consider the conditions of entrance to be one of the chief causes. A candidate can go up for his entrance examination between 21 and 28 years of age, but he must be under 25 years if he wants to obtain the chief advantages of the service and to run to the higher pensions; otherwise he comes under the "age clause" and the highest pension he can obtain is that of 25 years' service. Now, on looking through the newly qualified men of any school, many, if not most, of the best men—i.e., men who have qualified well and done a year or so in the house—are 25 years of age or thereabouts, and to these men the services are practically closed, as they cannot hope to run beyond a 25 years' pension. The consequence of this is that men intending to go into the services cram through the first double that they can get, their chief object being to enter early.

If this forced retirement at 55 years of age was done away with not only would a much larger field to recruit from be open, but a better class of man would come up, and also the man who now craves to get in early at any price might be tempted to be in less of a hurry and to do a year or so in the house before entering the service. The value of going into the house (either a house surgeoncy or a house physiciancy) is well recognised in civil life as being the best thing a man can do, but for a man going into one of the services it is the worst thing possible, as he loses seriously and may run over 25 years of age. If the abolition of the "age clause" was made retrospective and every man could complete his 30 years' service, the present want of men would to a large extent be reduced, as yearly many of our best men—anyway in the Indian Medical Service—are retiring at about 50 years of age who would gladly serve on could they run for a higher pension. If the "age clause" cannot be done away with as a whole could not men who have come in late due to passing some of the higher examinations or having done a house surgeoncy, &c., be exempted and be allowed to complete their 30 years and thereby obtain a better pension? Again, should a man enter late and during the time he is in the service he passes, say, his Fellowship (F.R.C.S. Eng.), could he not be exempted? If there were some conditions of this kind it would not only tempt better men, but might tend to keep many men already in the services in better touch with their profession. I am, Sirs, yours faithfully,

July 4th, 1901. I.M.S.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Increase in the Plague Epidemic.—The Invasion of Locusts.—The Increasing Famine and the Deficient Monsoon.—The Extinction of the Andaman Islanders.—The Crime of Poisoning in India.—The High Infantile Mortality in Bombay City.

THERE has been an increase of 138 deaths from plague throughout India during the past week. The deaths returned are 821 as against 683 for the week ending June 22nd. The development has occurred in the Bombay Presidency which records 651 deaths as against 471. There has been an increase of 17 in Bombay city, 12 in Bengal, and 20 in Mysore. Calcutta returns only 14 deaths and there are decreases in the North-west Provinces, the Punjab, Oudh, and Kashmir. Belgaum, on the borders of the Bombay Presidency, shows a distinct rise—viz., from 207 deaths to 276.

Locusts have appeared in several districts of India during the past week and have done an immense amount of damage. Indigo and other crops have been seriously affected and Makai and Cheena have been eaten up completely in places. Some of the flights are exceedingly dense and very large. The Government has warned district officers that the villagers should be organised to commence a campaign against young locusts as soon as they appear above the ground. The Cyprus screen and trap system has proved useless both in the Deccan and Konkan. Dr. Edington's method of inoculating with fungus is advised. One flight attacked an indigo ground four times on consecutive days, and in South Tirhut a flight was estimated at 14 miles broad and to have covered an area of 140 square miles. The country was red for miles—the indigo crop looking a browny red, having the appearance of being covered with red chillies. The swarms are evidently in search of a favourable breeding-ground. It takes the young locust 10 days after hatching before it can use its wings, and when in this stage it crawls about and eats up almost everything. Then is the time for its destruction.

Still another misfortune for India consists in the increasing famine. There are now over half a million persons in receipt of relief and the numbers rise higher week by week. The cost to the Government is 150 lakhs per month. The late monsoon and its great deficiency, except in the Peninsula, are a cause of still further anxiety.

The extinction of the natives in the Andaman Islands would seem to be only a work of time. The recent census tells the old story. Measles, pneumonia, and other introduced and contagious diseases have played their part, and as in the case of all diseases which find a susceptible race the percentage of mortality has been terrible. One tribe is said to have killed off every individual who was attacked by a contagious disease which had been introduced among them by a neighbouring coast tribe. Sterility seems also to have checked the population as the number of children is abnormally small. At the present rate of decrease some tribes will be extinct after three generations.

The record of a year's poisoning in the Bombay Presidency shows how extensive this practice is. Arsenic is the favourite agent, probably owing to the facility with which it can be procured and the rough similarity of the symptoms produced by it to those of disease. Major Barry records one case where two beggars were drugged with opium in order that they might be robbed of eight annas (8*d.*). The medico-legal cases referred to in the report only show the cases which are brought to light, but it is a common opinion that the crime of poisoning is excessively frequent. These remarks apply to nearly all parts of India. Copper, cerbera, dhatura, mercury, phosphorus, and ground glass are other poisons selected.

The high infant mortality in Bombay has been the subject of much recent discussion. From the census of 1891 the infant population (that is of children under one year of age) is estimated at 25,000. Before the advent of plague the birth-rate of Bombay city was fairly steady at about 18 or 19 per 1000 of the [illegible] a total of about 15,000 to 16,000 births [illegible] was an average rate of mortality of about 280 per 1000 of the infant population (about 7000 annual deaths). Since the year 1897 the birth-rate has declined to the rate of 12 or 13 per 1000, but the mortality has gone up enormously. In 1899 the rate rose to 530 per 1000. This is a frightful figure. The explanation given is that the disastrous famines cause a large inflow into the city of people in a low state of vitality. The sterilising influence of plague, as well as the exodus of people and the diminished population, may account for the diminished birth-rate, but the above reason hardly seems sufficient to account for the enormous difference in the death-rate. The health of Bombay has been in a bad state for some time quite apart from plague, but though the general mortality has been excessive it will not explain the doubling of the infant mortality. At the present time the general death-rate in Bombay is about 42 per 1000 per annum as compared with the rate of 64 for the corresponding period last year, so that the high infant mortality, coupled with a diminished birth-rate, requires further investigation.

July 6th.

THE BRITISH CONGRESS ON TUBERCULOSIS.

INAUGURATION OF THE CONGRESS: FIRST GENERAL MEETING.

THE British Congress on Tuberculosis was opened by H.R.H. the Duke of Cambridge, acting on behalf of His Majesty the King, on the afternoon of Monday, July 22nd. The inauguration ceremony was held at St. James's Hall, Piccadilly, W. The meeting was successful in regard to general attendance, while the cordiality of the welcome extended to the foreign delegates was unmistakeable.

The platform was crowded with well-known public men. Among those present may be mentioned most of the foreign Ambassadors, the Duke of Northumberland, the Marquis of Lansdowne, the Marquis of Bath, Earl Cadogan, the Earl of Derby, Earl Spencer, the Earl of Cawdor, Lord Lister, Lord Strathcona, the Bishop of London, the Lord Mayor of London, the Consul-Generals of the various colonies, and the Presidents of the great medical corporations and learned societies of the United Kingdom. The numerous official delegates to the Congress of the various foreign nations were all accommodated with prominent places on the platform.

Mr. MALCOLM MORRIS, at the request of the Duke of Cambridge, commenced the proceedings by reading his report as honorary secretary-general to the Congress. The movement, he said, originated in Berlin at the German Congress on Tuberculosis held in May, 1899, when representations were made to the British delegates as to the desirability of holding a similar congress in London. Some of these delegates were appointed by the Prince of Wales to represent the National Association for the Prevention of Consumption and Other Forms of Tuberculosis, and these reported the matter to the Council of that association. One of the objects of the association was the promotion of congresses for the dissemination of knowledge, and it was therefore resolved to take the necessary initiatory steps to hold a congress in London. The Foreign Office, the Colonial Office, and the India Office rendered every possible assistance. In Paris and in Berlin local committees had been formed to distribute information as to the objects of the Congress. At the request of the King the Duke of Cambridge had undertaken to fill the office of President of the Congress and to preside at that meeting.

The Duke of CAMBRIDGE, in rising to declare the Congress open, said that he hoped he would be forgiven by the assembly for undertaking a duty which he really felt unable to fulfil. The fact was that he was very much in the background with regard to all the interesting subjects of the Congress that had brought them together, but he felt a deep interest in them notwithstanding. He was gratified to see so large a number of delegates from foreign countries, and he appreciated the compliment that they paid to this country in attending. The Duke concluded by reading out to the meeting the following telegram which he sent to the King: "I have the honour to inform your Majesty that I have opened the Congress on Tuberculosis, which is largely attended by home and foreign delegates, in obedience to your Majesty's commands."

Lord LANSDOWNE then addressed the meeting and as one of His Majesty's servants welcomed the foreign delegates, saying on behalf of his colleagues in power that it would afford them the greatest pleasure, so far as their opportunities permitted, to give any facilities which His Majesty's Government was able to afford. The Government fully realised the immense significance of the problem which the Congress was attempting to solve.

Lord CADOGAN then spoke and claimed a *locus standi*, inasmuch as he represented Ireland, which country suffered perhaps as severely as any in Europe from the scourge they were met to consider and if possible to arrest. He was glad on behalf of the people of Ireland to add a few words of welcome to the Congress and especially to the foreign members who were to give them the benefit of their assistance on the occasion. It was generally known that the methods of dealing with tuberculosis in past years had not been successful, but it had of late been shown that methods would before long be found for dealing practically with its prevention.

The LORD MAYOR OF LONDON in a short speech welcomed the foreign delegates and the members of the Congress to the City of London and hoped that they would all come to the Mansion House on the following evening. The citizens of London, he said, regarded the objects of the Congress as second to none that could possibly be conceived in importance.

Lord STRATHCONA, who spoke for the Dominion of Canada, for the commonwealth of Australia, and for the colonies generally, said they were all united in an earnest desire that measures should be taken to grapple with a disease which had decimated the peoples of the world for centuries.

Lord LISTER pointed out that the Congress met under immeasurably happier auspices than could possibly have been the case a few years ago. They now knew, thanks to Koch, the enemy they had to deal with, while Pasteur had shown that the microbe of tuberculosis was incapable of originating *de novo* in the human body. Hence there was now the splendid prospect of the prevention of tuberculosis. Attempts were being made by the use of various specific means to deal with consumption even in its more advanced forms, and some of them at least had very promising aspects. If the prevention of tuberculosis was to be effectively carried out, the general public must aid the physician and the surgeon in their endeavours to immunise the people and so eventually to stamp out one of the greatest physical scourges of the human race.

The foreign delegates were then presented to the Duke of Cambridge by Lord Derby, and they addressed the meeting briefly.

Professor OSLER (America) thought that the Congress would educate the medical profession which needed education and the public which needed it far more.

Professor VON SCHROETTER (Austria) believed that the Congress would inaugurate a new and successful attack against man's greatest enemy.

Dr. MONTEFIORE LEVI (Belgium) attributed a large share in the success that had been attained to the active interest taken in the work by the Royal patron of the Congress.

Professor GRAM (Denmark) referred to the English people having taken the rose of Denmark for their Queen.

Professor BROUARDEL (France) said that the union of science and philanthropy marked a new phase in the contest against tuberculosis. He had been specially charged by the President of the French Republic to declare in his name that it was his earnest wish that the next Congress should be held in Paris in two years' time.

Professor VON LEYDEN (Germany) referred to the early work done by England in the prevention of tuberculosis.

Professor RUATA (Italy), after a graceful acknowledgment [illegible] concluded by expressing the [illegible] what she had done for the [illegible]

Mr. MALCOLM MORRIS then read a telegram from the King acknowledging the telegram from the Duke of Cambridge and heartily welcoming to his capital the eminent men belonging to almost every nation.

The proceedings came to a close with a hearty vote of thanks to the Duke of Cambridge for presiding, which was moved by Lord DERBY and seconded by Sir WILLIAM BROADBENT.

THE SECOND GENERAL MEETING.

Professor R. KOCH of Berlin addressed the members of the Congress assembled at the Second General Meeting in St. James's Hall, on Tuesday, July 23rd, Lord LISTER being in the chair. The title of his paper was "The Combating of Tuberculosis in the Light of the Experience that has been Gained in the Successful Combating of other Infectious Diseases." The address will be found in full at page 187.

The views expressed by Professor Koch in regard to the passing of tuberculosis from man to animals evidently attracted extraordinary attention and Lord LISTER'S speech as chairman was followed by the huge assembly with extreme interest, each point made by him being made the occasion for a burst of applause. The matter at issue, he said, was of great importance. If Professor Koch was right then preventive measures would be much simplified, but before the Congress could give its consent to the hypothesis the most complete investigations must be undertaken. Lord Lister before he resumed his seat instanced the infection of the mesenteric glands from bovine tuberculosis in support of his contention that the evidence advanced by Professor Koch was not conclusive.

Professor **Nocard** (Alfort) spoke as a member of the veterinary profession in France and described how the exaggerated fears of tuberculous infection from animals had raised a movement which they had only just begun to encounter with success, and now it would appear as if the swing of the pendulum might take them dangerously far in quite the opposite direction. Professor Nocard discussed the subject of the possibility of infection of man by bovine tuberculosis and cited cases where veterinary surgeons had become thus inoculated by accident.

Professor **Bang** (Copenhagen) in a few words warned those present that though Professor Koch had shown that there was only slight danger of infecting animals from man, nevertheless the inoculation of man from animals was a different matter, and in his opinion Professor Koch went too far in saying that there was no necessity for taking measures against bovine tuberculosis.

The meeting ended by Professor **Sims Woodhead** pouring oil on the troubled waters. He did not consider that Professor Koch's views were so violently opposed as they appeared to be to modern pathology. In the course of his remarks he described a specimen exhibited in the museum of the Congress which proved that it was possible for human beings to be infected with tuberculous disease from animals.

The Third General Meeting.

The Right Honourable **Henry Chaplin**, late President of the Local Government Board and of the Board of Agriculture, presided over the third general meeting of the Congress on Wednesday afternoon in St. James's Hall.

Mr. **Chaplin**, in introducing Professor Brouardel to the meeting as the President of the Paris Society of Medicine, said that as the leading medical adviser to the French Government he might be considered to rank among the highest living sanitary authorities. He remarked that hitherto the opposite of Professor Koch's views had been the accepted doctrine—viz., that bovine tuberculosis is transmissible to man through the flesh and milk of cattle. Professor Brouardel then delivered his address which will be found in full at page 191 of The Lancet.

THE SECTIONS.

The work of the various sections commenced on Tuesday, July 23rd, at 9.30 A.M.

SECTION I.

State and Municipal.

Tuesday, July 23rd.

The meetings of this section, in many ways the most important section of the Congress because of the vast public interests involved in the discussions, were held in St. George's Hall, Langham-place, W.

The proceedings were opened at 9.30 A.M. on July 23rd by the Right Honourable Sir **Herbert Maxwell**, Bart, P.C., M.P., F.R.S., with a short address. He said:—

No one in this room could feel more his own unfitness for discussing the matters which are to be brought under the consideration of this Congress than I, being myself wholly without previous special training. I trust, therefore, you will regard me only as a link, however weak, between scientific research and the legislative machine which it is the fashion of men of science to set in motion. We sometimes hear complaints, especially in this country, that the legislator does not keep abreast with the advance of science. I would remind you that men of science must be in a great measure pioneers. Pioneers have to retrace their steps sometimes. That is why we appear to be laggard in the advance. However unfit I am to discuss the subjects proper to the Congress there is one thing which at all events I may venture to say, and that is to bid a hearty welcome to those ladies and gentlemen who have travelled, many of them from far foreign countries, to take part in the business of the Congress. In one respect I am afraid our welcome to our foreign guests must partake of the nature of an apology. Those who were present at the great Congress in Berlin in 1899 must cherish a warm recollection of their reception there; the princely hospitality displayed to them, the liberal manner in which the great building of the Reichstag was placed at their disposal for the transaction of the business, and, above all, the warm personal interest displayed by the German Emperor, his Empress, and the Ministers of State. The circumstances of mourning under which this country lies at present owing to the death of our good Queen have rendered it impossible for King Edward VII. and his Government to impart to your reception in this country and in this metropolis that degree of warmth which, under other conditions, would have been most natural and fitting. I pray you, therefore, gentlemen from foreign countries, to bear this in mind and to make allowances for any shortcomings in your reception here on the present occasion.

I have spoken of you as foreigners, but I do not forget that in science and philanthropy there are no physical frontiers separating nation from nation. We work hand-in-hand in the common cause without jealousy, though emulating one another in the search for truth, and looking for no reward save in the common welfare of the community. It is not unfit perhaps on the threshold of your labours that I should remind you of the vast advance that has been made in the past, and of the presence of Professor Koch among us who was the first to specify the bacillus of the disease under consideration. Rapid progress as we have made, far more lies before us. If I venture to touch upon two points which will come under your notice it is not because I assign to them a higher importance than the other matters which will be considered, but it is because as an unprofessional man certain points must present themselves to me with greater distinctness than others. There is the great question of the notification of consumption on the paper for discussion to-day. Upon that point I would ask you to bear in mind how impossible it is to induce an uneducated and self-governing community to adopt restrictions and precautions unless and until they comprehend the nature of these precautions and share in the understanding that they will be effective. Our experience in this country in the matter of compulsory vaccination will I am sure make the legislators extremely shy of making any step in the direction of control of tuberculosis unless they feel that they have the weight of public opinion behind them. I need not labour that point. As far as Great Britain is concerned let the people in this country thoroughly grasp the facts (1) that the returns show that the mortality from tuberculosis has been diminished from 38 per 1000 in 1832 to, I think, 14 per 1000 of the population in 1894, and (2) that tuberculosis still remains answerable for a greater share of the mortality in this country than all the other most dreaded infectious diseases put together—let them once thoroughly comprehend that much and, speaking from a considerable knowledge of my own countrymen, I venture to say that no insuperable difficulty will be found in the way of general notification. My other point is a minor one. It is in connexion with the subject of the influence of housing and aggregation of population. There is a thing which is apt to be overlooked. Our Scripture says: "Dust thou art and unto dust shalt thou return." and in our praiseworthy efforts to delay that return as long as possible we have come inevitably to the conclusion that there is no more potent agency in the dissemination of disease than dust itself, and no such potent agency in the sterilisation of that dust as abundant sunlight. What I wish to bring out is this, that while we have spent large sums of money in bettering the houses of the working classes we are face to face with a new danger. In our great commercial centres, where land is measured and valued at so many guineas to the square foot, the tendency must be to pile up houses higher and higher and so to exclude that priceless agent the sunlight. I think it is worth the attention of municipalities and other governing bodies to deliberate whether some restriction should not be imposed upon architects and builders so that the height of the houses should be on a definite proportion to the width of the streets. I anticipate most valuable and practical results from the conclusions to which you will come. You have to consider and advise what part the State and municipality are to bear in putting into practical effect the discoveries of science.

The work of the section was arranged under five divisions—viz. (1) Statistical; (2) Notification of Tuberculosis; (3) Influence of Housing and Aggregation; (4) International Aspects on Tuberculosis; and (5) Provision of Sanatoria.

Division I., Statistical.

Dr. **John Tatham** of the General Register Office, Somerset House, opened the business of this section by communicating a

Memorandum on Mortality from Tuberculous Phthisis in England and Wales during the last 40 years.

The mortality from phthisis at all ages in the four years, from 1896 to 1899, he said, was equal to a rate of 1521 per

1,000,000 living among males, and to a rate of 1141 per 1,000,000 among females. Among male children under five years old the rate was 403 per 1,000,000, and among female children it was 334. Male children aged from five to 10 years died at the rate of 140 per 1,000,000, and female children of the same age at the rate of 201 per 1,000,000. At the ages from 10 to 15 years the male rate was 195 and the female rate 410 per 1,000,000. In both sexes the real liability to phthisis began somewhere between the fifteenth and the twentieth year. Among males the death-rate at the age-group from 15 to 20 years stood at 908 per 1,000,000, and attained its maximum at the age-group from 45 to 55 years, when it reached 3173. Among females at the age-group from 15 to 20 years the rate was 1165, and attained its *maximum* (2096) at the age-group from 35 to 45 years. In both sexes the rate rapidly declined after the attainment of its maximum. Practically the incidence of phthisis was upon the ages from 15 to 75 years, very old people and young children being comparatively exempt. According to recent experience females seemed to be rather *less liable* than males to death from phthisis at ages under five years, *more liable* at the age from five to 20 years, and again *less liable* at subsequent ages Liability to fatal phthisis appeared to commence somewhat earlier in females than in males.

Changes in Mortality from 1851 to 1899.—Table A indicated that, with a few trifling exceptions, every age-group in both sexes had experienced *a decrease* in the mortality ascribed to phthisis. In every case the mortality in 1895-99 was lower than it had been in 1851-60; but the rate of decrease had varier widely and had been much greater among females than among males. The reduction indicated by the table might not be wholly real and might be due, in part, to the vaguer statement of causes of death in the earlier period, as, for instance, by the habitual use of the terms "consumption" and "decline" to describe any lingering disease of the lungs attended by "wasting." The figures must therefore be taken for what they were worth. Comparing 1896-99 with 1851-60 it was found that mortality from phthisis in males *at all ages* had been reduced from 2579 to 1521 per 1,000,000, and in females from 2774 to 1141 per 1,000,000. At ages under five years the mortality of males had been reduced from 1329 in the earlier period to 403 in the later and that of females from 1281 to 334. At the age-group from five to 10 years the rate had fallen from 525 to 140 among males and from 620 to 201 among females. At the age-group from 10 to 15 years the male rate, which in 1851-60 had been 763 per 1,000,000, had been reduced to 195, and the female rate, which had been 1293, had been reduced to 410. From 15 years upwards the female rate had fallen more than had the male rate. From 25 years to the end of life the male rate had fallen in varying proportions. The fall in the female rate at the successive age-groups after 25 years had not differed greatly from one-half. Tracing backwards the incidence of maximum mortality from phthisis it was found that it had not always been at ages from 45 to 55 years for males and from 35 to 45 years for females as it was at present. In the decade 1851-60 the mortality from phthisis was at its highest among males at ages from 20 to 25 years and among females at ages from 25 to 35 years. Thus the age of maximum phthisis mortality had been postponed in both sexes. In other words, either the saving of life had [illegible] which were formerly most liable to [illegible] or persons [illegible] they would have done [illegible]

Dr. Tatham also submitted two other tables. One of these (Table B) compared the mortality from phthisis in 1881-90 with that in 1895-99 in each of the registration counties of England and Wales, showing the proportional decrease in the phthisis-rate of each county in the later four-year period as compared with the earlier decennium. The other showed that the mortality from phthisis was also very seriously affected by occupation. Thus among people presumably not widely different in respect of social position—such as tin miners and coal miners—a number of males living at ages from 25 to 65 years, which gave 508 deaths from phthisis among tin miners, gave only 69 deaths (or only one-seventh part) among coal miners.

Dr. JOSEPH VON KOROSY (Budapest) read a paper on

Some Observations on the Influence of Social Standing, Food and Paternal Age on the Occurrence of Phthisis,

of which the following in an abstract. He said:

"1. *Occupation.*—During the period 1874-90 I observed the connexion between occupation and causes of death of 57,910 males and 49,034 females who died at ages above 15 years. According to these observations we may state that consumption caused death most frequently amongst printers, among whom in this period of 17 years 60·6 per cent. died from consumption; thus it may be considered as an exception if any printer died from another cause of death than phthisis. The next most fatal groups, with a mortality of nearly 50 per cent, consist of butlers, 52 per cent., shoemakers, dyers, and millers, 49·4, 49·3, and 49·2 per cent.; joiners, tinkers, and locksmiths, 48·5 and 48·4 per cent.; masons, 46·7 per cent.; working men, 43·3 per cent.; tailors, 41·8 per cent.; bakers, 39·8 per cent.; journeymen, 39 8 per cent.; drivers, 37 per cent.; servants, 36 per cent.; carpenters, 33·9 per cent.; officials, 33·6 per cent.; butchers, 33·3 per cent.; merchants, 28·3 per cent.; innkeepers, 27·2 per cent.; and lawyers, 20·5 per cent. Consumption appeared most rarely amongst capitalists, 10·6 per cent. of the deceased, and amongst physicians, 11·8 per cent. Amongst females more than half (51·2 per cent.) of the deceased died from phthisis; amongst working women nearly one-third; amongst female servants, 35·3 per cent.; female day-labourers, 33·3 per cent.; washerwomen, 31·4 per cent.; but only a quarter died amongst female gardeners (26·9 per cent.), and amongst capitalists, 4·2 per cent. But in face of such observations we can hardly neglect the influence of the different distributions of age within the different occupations. We know that the appearance of consumption depends largely upon age, occurring the most frequently with and after the age of puberty, and reaching its maximum between the thirtieth and fortieth year of age. Thus it is desirable to study the appearance of this cause of death separately with the different classes of age. This I was able to do from the year 1882, but, to my regret, only for the following ages: 15–30, 30–50, and above 50 years. Amongst 100 deceased of the following occupations who died at the age of 30–50 years, the number of consumptives was: (*a*) Males—(1) physicians, 15·1; (2) lawyers, 29·4; (3) capitalists, 30·4; (4) merchants, 35·3; (5) innkeepers, 37·0; (6) officials, 37·5; (7) butchers, 41·4; (8) journeymen, 42·0; (9) drivers, 42·6; (10) workmen, 45·3, (11) bakers, 48·5; (12) butlers, 50·8; (13) carpenters, 50·9; (14) servants, 51·3; (15) tinkers and locksmiths, 53·1; (16) tailors, 53·6; (17) masons, 53·7; (18) dyers, 55·2; (19) printers, 55·9; (20) shoemakers, 56·1; (21) joiners, 57·7; and (22) millers, 59·9. (*b*) Females—(1) journeywomen, 48·0; (2) servants, 38·9; (3) capitalists, 69·3; (4) needlework women, 65·6; (5) washerwomen, and (6) gardeners, 48·1

2. *Religious profession.*—The frequency of consumption was in the average of the five years 1885–93 out of 100,000 living people: amongst Roman Catholics, 722; amongst Lutherans, 788; amongst Calvinists, 559; Protestants, 625; amongst Jews, 376.

3. *Death.*—Out of 100,000 wealthy deceased there were swept away by consumption 15,943, whilst out of 100,000 poor persons, 22,339. Thus we may say that phthisis causes amongst poor people 40 per cent, more deaths than among the wealthy.

4. *Food of children.*—During the seven years 1882–90, observations were made with regard to bringing up of 37,313 children deceased at the age of 0–2 years. The points noted were whether the children were brought up at home or not, and whether they were nourished at the breast or bottle-fed. The results of these observations are as follows:—

—	Brought up in the family.		Out of the home.		Total.	
	Number of the deceased.	Out of these died from consumption.	Number of the deceased.	Out of these died from consumption.	Number of the deceased.	Out of these died from consumption.
Fed at breast ...	29·679	1570	1038	90	30,717	1660
Artificially ...	5·461	348	1135	185	6,596	533
Total	35·140	1918	2173	275	37,313	2193

Thus we find that amongst 100 deceased children there died from consumption: if brought up in the family, 5·4 per cent.; if out of home, 8·9 per cent.; if fed at breast, 5·4 per cent.; and if nourished artificially, 9·5 per cent. Combining the two conditions we find:—

	Nourished at breast.		Nourished artificially.
At home	5·2 per cent.	....	6·4 per cent.
Out of home ...	8·7 „	....	16·3 „

Thus, the cases of phthisis amongst the children brought up artificially out of home was three times greater than amongst family children nourished at the breast.

5. *Influence of paternal age.*—The following results I quote from my paper read at the London Congress of Hygiene and Demography. "It refers to 10,385 children deceased at the age of 0–10 years and observed according to the age of father and mother. I found that amongst 100 deceased children the number of consumptives was, at the maternal age of: under 20 years, 8·45; under 20–30 years, 5·09; under 30–35 years, 2·78; above 35 years, 4·26. Thus, consumption appeared the most frequently amongst children of very young mothers, whilst the frequency of it diminished with middle-aged mothers, and rose again with mothers above 35 years. According to the father we find also that the youngest and the eldest show a greater number of tuberculous children—viz., at the paternal age of: under 25 years, 5·71; under 25–30 years, 4·74; under 30–40 years, 3·61; and under 40–50 years, 6·01."

DIVISION II., THE NOTIFICATION OF TUBERCULOSIS.

A paper by Dr. HERMANN BIGGS (New York) upon

The Voluntary Notification of Advanced Tuberculosis

was then read by Dr. Janway. The author showed how this could be best encouraged and effected and what had been the experience of compulsory notification in the cities of New York, Buffalo, and Washington.

Alderman MCDOUGALL (Manchester), Deputy-Chairman of the Sanitary Committee and Chairman of the Hospitals Sub-Committee of that city, then read a paper on

The Working of the Voluntary Notification of Phthisis in the City of Manchester.

Early in 1899, he said, a scheme for the voluntary notification of phthisis was submitted to the Sanitary Committee of the City of Manchester and was accepted by them. By that committee a statement was placed before the City Council limiting the notification of cases to public institutions in the first instance. This proposal was accepted by the City Council who also accepted the entire scheme, though not for immediate execution. A highly qualified medical man, Dr. Coates, was appointed in September, 1899, to assist the medical officer of health in administering the scheme. In March, 1900, the city council accepted the further proposal that medical practitioners should be invited to notify their cases, and a second medical assistant, Dr. G. F. McCleary, was appointed. It was understood that the objects of notification were to be: (1) that the medical assistant should visit the homes of cases and instruct the household in the precautionary measures to be adopted, leaving with them printed instructions; (2) that they should determine what measures of disinfection were required; (3) that they should make inquiries into the exposure to infection of individual cases from relatives, workmates, friends, &c., into their occupations and places of work, the various houses which they had inhabited, their physique, personal habits, and so forth—in fact, into every circumstance which might be supposed to bear on the modes of infection; (4) to sustain a supervision over infected households, to ascertain change of address, and to see that personal precautions and household cleanliness were maintained and to get necessary measures of disinfection carried out from time to time; (5) to provide for the required measures of disinfection being executed; (6) to assist in getting bacteriological examinations of sputum in suitable cases; and (7) to collect information regarding households which might serve as a basis for hospital provision. To assist the medical officer of health in carrying out the scheme, besides the two assistant medical officers, there were available the services, in part, of 28 district sanitary inspectors and of 19 health visitors belonging to the Manchester and Salford Ladies' Health Society and to the Jewish Ladies' Health Society, voluntary organizations aided by the corporation. By these the cleansing and disinfecting work had been supervised and a continuous supervision had also been exercised over cases once reported. The administrative work had also required the time of two clerks in writing letters, entering records, and so forth. The following figures would serve to give an idea of the amount of work which had been done. The number of cases notified from September, 1899, to the end of March, 1901, had been 2338. Of these, 931 had been notified from hospitals and 779 had been notified from public institutions (628 by private practitioners); total 1710. During that period the number of deaths registered from phthisis had been 1729. The total number of houses disinfected between March 31st, 1900, and March 30th, 1901, had been 2306 The methods of disinfection employed had been to disinfect articles of clothing by steam, while rooms had been disinfected by washing the floors, woodwork, &c., with soft soap and water, cleansing the walls down with dough (Esmarch's method), and limewashing the ceiling. If, however, the house was dirty, or the patient had not carried out careful personal precautions, or marks of sputum were visible on the floor or walls, the surfaces of the room were washed with a solution of chlorinated lime (one and a half ounces to the gallon). This method was adopted as the result of a special investigation by Professor Delépine. The amount of disinfection done was shown by the following figures, which, however, included disinfections after death. By corporation, with chloride of lime solution, 633; by corporation, with solution of lime, 94; chiefly by tenants, by Esmarch's method, 1579; total, 2306. He might mention that they had begun the isolation of advanced cases of tuberculosis from crowded houses, though only about a dozen were as yet actually isolated. The number of applicants for admission was large and the need for the reception in hospital of such cases was very great. With the new hospital given by Mr. Crossley the number of beds available for Manchester and district would be—sanatorium, 120; isolation, 12. To these must be added the provision made by the union hospitals and such additional provision as the corporation might make. As regards the union hospitals, he was of opinion that the taint of pauperism should be removed altogether from the sick.

Dr. M. HOLMBOE, Director of the Medical Service in Norway, then read a paper on

The Notification of Tuberculous Diseases in Norway.

He said that according to the law of May 6th, 1900, which law came into force on Jan. 1st of this year, compulsory notification of such cases of tuberculosis, which were accompanied by secretions, had been introduced in Norway. Subject to notification were: (1) new cases of such disease coming under medical treatment; (2) deaths of persons suffering from such disease; and (3) changes of residence of such persons, if it should be so agreed by the municipal council and approved by the Government. The notifications were to be given to the officer of health of the place who in Norway always was a physician; these notifications had a confidential character. The compulsory notification had been introduced in order to give the officer of health an opportunity to see that necessary cleanliness was observed in the homes of the sick, especially in the treatment of their secretions, and that a radical cleansing was made of their rooms and their garments and bedclothes before others made use of them. The law had been too short a time in force to allow anything to be said with certainty about its effects. At any rate, no complaint against inconveniences resulting from the compulsory notification had yet come to the notice of the directorate of the medical service.

Discussion on Prevention of Tuberculosis during Childhood.

Dr. S. A. KNOPF (New York) read a paper

On State and Individual Prophylaxis of Tuberculosis during Childhood and the Need of Children's Sanatoria,

of which the following is an abstract. In the first portion of the paper Dr. Knopf refuted the conception of frequent hereditary transmission of the bacillus tuberculosis and demonstrated that post-natal infection was virtually the only source of tuberculosis in infancy and childhood. He described the manner of how the child in the home of an unclean, ignorant, or careless consumptive had multiple chances of taking the disease into his system by inhalation, ingestion, and inoculation. The contraction of tuberculosis through the ingestion of milk and other food substances derived from tuberculous cows was also briefly treated. The precautions which should be taken to avoid the infection of the child from tuberculous parents and others living in the family were described in detail and so were the kind of leaflets concerning the prevention of tuberculosis which health boards should gratuitously provide to physicians, midwives, and mothers. Dr. Knopf's views concerning the so-called hereditary predisposition were set forth and may be summarised here by saying that there was inherited very often from a tuberculous mother, much more rarely from a tuberculous father, a physiological poverty which might handicap the offspring in its development and offered when occasion presented itself a suitable soil for the invasion of the bacilli of tuberculosis. Dr. Knopf was, however, convinced that many of these children, born "tuberculisable," could be protected from contracting the disease by being placed from early childhood in proper sanitary surroundings and given a prophylactic, hygienic, and dietetic treatment. Respiratory exercises for the development of the lungs were, in the opinion of Dr. Knopf, of great importance in this prophylactic treatment. The hygienic and dietetic treatment should, however, begin with the mother while the child was still in utero. The most healthful life, generous diet, comfortable garments, and breathing exercises in the open air should be prescribed for the mother during the state of pregnancy. The duties of the State and municipality in the prevention of tuberculosis in children were outlined, and the urgent need of children's sanatoria, to which schools should be attached, for tuberculous children was dwelt upon.

The French School Colonies.

M. RAOUL BOMPARD (Paris) contributed to a discussion on prevention of tuberculosis in childhood a paper on the above subject. He said that the poor child, badly nourished and overworked, was particularly liable to tuberculosis. They endeavoured in France to insure to the largest possible number of poor school-children a sojourn in the country, either at the sea or among the mountains. This project had been zealously carried out by a great number of private enterprises and by the municipalities of Bordeaux, Lyons, Marseilles, Roubaix, Lille, Agen, and Toulon Paris devoted 279,000 francs (£11,160) a year to this object, by which more than 4000 children profited. The average length of stay was three weeks. Some societies and municipalities had bought villas to insure a longer stay for the anæmic cases. The average benefit derived was estimated approximately at an increase in weight of two kilogrammes and an increase round the chest of two centimetres.

WEDNESDAY, JULY 24TH.

DIVISION III., THE INFLUENCE OF HOUSING AND AGGREGATION.

Dr. HAROLD COATES (Manchester), senior assistant to the medical officer of health of that city, communicated to the section the results of an investigation, undertaken at the suggestion and under the direction of Dr. Niven and Professor Delépine, into

The Presence of Infective Material in Dwellings occupied by Consumptive Persons.

In 1895, he said, an investigation of this kind was commenced under the direction of Professor Delépine at Owens College but was shortly after abandoned. The establishment of a scheme of voluntary notification of phthisis in 1899 presented a favourable opportunity for taking up the investigation, and, acting on the suggestion of Dr. Niven, the hospitals sub-committee of the Manchester Corporation resolved that he (Dr. Coates) should carry out the work under the direction of Professor Delépine. Although the plan of the investigation was somewhat different the methods of experimentation pursued were in the main similar to those of Cornet, although modified in some respects at the suggestion of Professor Delépine. Specimens of dust were collected from situations in which dust from the atmosphere had settled naturally and where there would be no likelihood of direct contamination with expectoration or by infected articles. The dust was taken from the floors, crevices between the boards and between the floor and skirting board, from shelves and other similar situations, by means of a metal spatula, which was sterilised immediately before use by passing it several times through the flame of a spirit lamp until red hot and then allowing it to cool. By means of this sterilised spatula the dust was placed in a glass tube plugged with cotton-wool, which had been previously sterilised in the autoclave, the cotton-wool plug being passed through the flame of the spirit lamp when opening and replugging the tube. The tube containing the dust was then carried in a sterilised metal box to the laboratory. Small pieces of sterilised sponge carried in sterilised glass tubes plugged with cotton-wool were rubbed vigorously over an area of two square feet of wall surface and then replaced in the tube and the tube replugged with cotton-wool. The cotton-wool plug was passed through the flame on opening and replugging the tube. Sometimes.

two or more pieces of sponge would be used for the same area of wall surface if this happened to be very dusty. The tube containing the sponge was then placed in a metal box and carried to the laboratory. According to Cornet's estimate the dust collected by rubbing over two square feet of wall surface would be the deposit from at least 306 cubic feet of air. On arrival at the laboratory the dust, or dust-laden sponge, as the case may be, was well rubbed up with sterilised water, and the mixture filtered through sterilised muslin, so as to remove coarse particles which might otherwise block up the needle of the hypodermic syringe used for inoculation. The emulsion thus obtained was centrifugalised and a small portion of the deposit, spread on a covered glass, stained and examined microscopically for tubercle bacilli. In only two cases out of a very large number of film preparations of the dust examined microscopically were tubercle bacilli discovered. This method was therefore practically useless for the discovery of tubercle bacilli in a specimen of dust. Cultivation methods were also useless because the dust contained many other organisms which would overgrow the slowly growing tubercle bacillus. The method employed to determine the presence or absence of tubercle bacilli in the dust was that of the inoculation of a susceptible animal—viz., the guinea-pig. The site of inoculation was on the inner aspect of the left leg, just above the level of the knee-joint, the pathological changes produced by the inoculation of tuberculous material in this situation being very definite and constant. The houses in which investigations were carried out were classified into the following groups: 1. Houses which were in a dirty condition and in which a consumptive patient was living who was taking no precautions to dispose of his expectoration so as to prevent infection of the atmosphere, but who spat freely on to the floor or into his pocket-handkerchief, &c. 2. Houses which were in a very clean condition but in which a consumptive patient was living who was not sufficiently careful as to the disposal of his sputa. 3. Very dirty houses, in which there had been no case of tuberculous disease for several years past. As a result of the inoculations many of the animals died from acute septic diseases. Those which survived were killed about one month after the inoculation and at once dissected so as to show the lymphatic ganglia and viscera. Any morbid changes were noted in a book kept for the purpose and cover-glass preparations were made from scrapings of affected glands and organs and examined for tubercle bacilli.

Of houses belonging to Class I.—infected houses in a dirty condition—23 were examined. Two of these houses had to be excluded from consideration because the results were inconclusive. All the animals died shortly after inoculation and microscopic examination of the dust was fruitless. In another house both animals died shortly after inoculation; but in this case examination of the dust revealed the presence of tubercle bacilli, and this may be accepted as evidence that the dust was infective. Therefore there are 21 houses in which definite results were arrived at. In 13 of these houses at least one animal was found to be tuberculous, and in another house tubercle bacilli were present in the dust. Therefore in 14 out of the 21 houses—i.e., in 66·6 per cent.—the presence of infective dust was proved which had at one time been suspended in the atmosphere and therefore was capable of being inhaled. In seven of the houses there was no evidence that the dust was infective. Altogether, 52 guinea-pigs were inoculated with dust from these houses; 20 of these died within a few days of inoculation, 17 were killed from four to five weeks after and found to be tuberculous, and 15 were killed from four to five weeks after and found to be healthy. Taking the conditions of lighting and ventilation in the 21 houses which gave results either negative or positive, they found that out of the 14 "positive" houses the lighting and ventilation were bad in eight houses, fair in one house, and good in only five, while of the seven negative houses the lighting and ventilation were good in six and fair in the other one. In *none* of the houses with negative results were the lighting and ventilation poor or bad. These facts pointed strongly to the beneficial effects of light and air, even in the dirtiest houses, where the conditions were certainly not favourable to their action. As was to be expected, those samples of dust taken within one or two feet of the floor produced tuberculosis oftener than samples taken at higher elevations. This greater infectivity of the dust nearest the floor was not due to direct infection with sputum, as all the samples were collected from places where this could not occur.

Of houses belonging to Class II.—clean but infected houses in which a consumptive patient was living who was not sufficiently careful as to the disposal of his expectoration—ten houses were brought under examination and two samples of dust were taken from each house. Each sample was used to inoculate one guinea-pig. Microscopical examination of the dust was not carried out in these experiments, as the results in previous experiments were so very unsatisfactory. 20 guinea-pigs were inoculated, and of these *only* three died from acute diseases shortly after inoculation. Of the remaining 17 animals, six developed tuberculosis and 11 were found free from tuberculosis at the post-mortem examination. Of the 10 rooms examined, dust capable of producing tuberculosis on inoculation into a susceptible *animal* was *found in five; in one* case both animals belonging to that room became tuberculous; in the other four rooms one animal only became affected. Thus even in the cleanest of houses infectious dust could be found in 50 per cent. of cases when the phthisical occupant was using his pocket-handkerchief or the floor as a receptacle for sputum. It was therefore evident that ordinary cleanliness alone was not sufficient to prevent the accumulation of infectious material in the rooms occupied by a consumptive. Taking the houses of Class I. and Class II. together, the influence of sunlight and fresh air in the prevention of accumulations of infective dust was shown very markedly.

Ten houses were examined of Class III.—dirty houses in which no case of tuberculosis was resident—and in no case was any tuberculous dust discovered. Twenty guinea-pigs were inoculated with dust taken from these houses, and six of these died within a few days of inoculation. The remaining 14 were killed from four to five weeks after inoculation, and all were found to be free from tuberculosis. These results, taken in conjunction with the results obtained from houses in Class I. and Class II., showed that the virulent dust found in those houses was due to the presence of a consumptive patient who was infecting the atmosphere with his expectorations. These experiments showed that living and virulent tubercle bacilli were present in the dust, which had deposited itself naturally from the atmosphere, in rooms which were occupied by phthisical patients who were in the habit of spitting upon the floor or into pocket-handkerchiefs. They also seemed to show that this infective dust was present in greatest amount or was most virulent where the access of sunlight and the free circulation of air were prevented. Such infected rooms must be a source of danger to those occupying them. Healthy persons ran the risk of being infected and the patient himself might become reinfected and his ultimate recovery be delayed or prevented.

The paper concluded with a description of the methods of disinfection in use in Manchester.

Professor von Schrotter (Vienna) said that the best method of getting rid of tuberculous sputum was by burning it. The sputum of patients walking about was collected in a modification of Dettweiller's bottle and that of those lying in bed in papier-maché spittoons containing powdered turf. The contents of the bottles and the spittoons themselves were well mixed with turf and then burnt.

Dr. J. Robertson, medical officer of health of Sheffield, then read a paper on the

Influence of Housing and Aggregation on the Prevalence of Tuberculosis.

There was at the present time, he said, ample evidence that the lighting, ventilation, and cleanliness of a large proportion of dwelling-houses, factories, and workshops were not sufficiently good to secure that degree of good health which was necessary in order to prevent the occupiers and workers being attacked by tuberculosis and other diseases. Again, there had been accumulating during past years ample evidence that, given good conditions as regards light, ventilation, and cleanliness of dwellings and work-places, the amount of tuberculosis was very much less than in places where the lighting, ventilation, and cleanliness were deficient. There was also the evidence of the mortality statistics during the last 40 or 50 years, which showed that, without any direct effort in regard to phthisis, the disease had diminished by over 45 per cent., and that in the case of all forms of tuberculosis in the human subject the decrease had been during 40 years something like 40 per cent. This diminution in the number of deaths from tuberculous disease had been coincident with a general improvement of the sanitary conditions of the people. The condition of houses in every respect was better now than it was 50 years ago; so also there had been an enormous improvement in the conditions under which a large proportion of the labouring classes worked. This improvement was not only an improvement in the sanitary condition of the work-places in its ordinary sense, but also in regard to those special processes, such as grinding, where dust or fumes had a deleterious influence on the respiratory organs. There had also been an enormous improvement in the food-supply of the working-classes. So far as the removal of refuse in towns was concerned the improvement had been steady and was continuing at the present time. It was questionable, however, whether the cleanliness inside the dwelling-houses of the people was better now than it was 50 years ago, when so much larger a proportion of the population lived in rural areas. Personally, Dr. Robertson was inclined to think that the condition of the people as regarded cleanliness of dwelling-houses was better now than it was formerly. There could be no doubt that the general cry for the abolition of slums and the adoption of women inspectors to look after the conditions inside the dwelling-houses had been productive of good, and would continue to improve their conditions in this respect. If further evidence were required, there had been accumulating during the past 10 or 15 years an enormous amount of evidence which was extremely valuable from the point of view of preventive medicine—viz., as regarded what could be done in preventing tuberculosis in the lower animals. It had been demonstrated so frequently that the proper housing of cattle to a large extent prevented tuberculosis that it had now become almost common knowledge in the medical and veterinary professions. The demonstration that tuberculosis among cattle was not in itself hereditary was also highly important. The prevention of tuberculosis divided itself roughly into two divisions: (*a*) the prevention of the spread of infecting material, and (*b*) the strengthening of the resistance of every individual, and especially of those having a hereditary tendency towards the disease. The number of persons who had some hereditary history or hereditary tendency towards tuberculosis was extremely large—so large, indeed, that it was impossible to limit one's action in strengthening resistance to any particular group of persons. While one advocated by all means the limitation of infecting material it was even more important to be able to put this large group of the community into such a condition of environment that there would be less tendency to develop the disease. The possibility of being able to do this appeared to be a very hopeful one. No one who had had to watch delicate consumptive patients undergoing the open-air treatment for tuberculosis could doubt for a moment that fresh air, sunlight, and good food had a most potent influence on the disease. Nor could any careful observer doubt that the persons who lived and worked under good conditions as regarded air and light were very much less susceptible to tuberculosis than those living and working in ill-lighted premises. The lighting of any house or work-place did not depend alone upon the area of window, and until some good means of measuring light was obtained there would probably be little improvement on the present condition. A film of tar or soot on the windows of a town house would cut off nine-tenths of the photographically active light; a dark stone or brick building adjacent to a house would absorb nearly twice as much light as a light-coloured one. Except in the centre of cities, it was advisable that there should be no building which obstructed the light from another, no cellar dwellings should exist, and no cellars should be allowed to be used as work-places. The effect of dark offices and workshops upon the young people employed was remarkable, and there seemed to be absolutely no reason why such premises should be allowed to damage the health of the occupiers. The very difficult subject of ventilation was largely neglected in this country, owing chiefly, no doubt, to the variable temperature. Yet by insisting that workers, and especially those engaged in sedentary occupations, should carry on their work in a good atmosphere they would do more in the way of increasing the resistance against tuberculosis than by any other single means. There was difficulty in quite understanding why the small increase of carbonic acid and other impurities which occurred in a badly-ventilated room should have such a powerful effect, but that it had a powerful effect no one who had observed carefully for himself could doubt. The present cubic air-space permitted by statute in the case of factories and workshops was too small for efficient ventilation. Personally, Dr. Robertson felt very strongly that the only way to ensure proper ventilation was to insist upon a high standard of purity of air, but the difficulty in the adoption of such a standard was the very varying methods used in the estimation of carbonic acid in the air. At the present time a large number of workshops and factories never had their floors and benches washed, and yet there was no more reason why this should not be done than in the case of common lodging-houses. There were, of course, a certain number of trades where earth floors were a necessity; in all others there should be a requirement that the wood-work and floors should be washed once a week. Such a condition of cleanliness in work-places would not only be of value in itself to the workers, but would be an object-lesson of considerable importance.

Discussion on Higher Standard of Lighting and Cleanliness.

Dr. A. RANSOME, F.R.S. (Bournemouth), communicated a paper on

The Need of a Standard of Efficient Ventilation,

of which the following is an abstract. He said that consumption was a "filth disease" and flourished in atmospheres polluted with organic matter, especially of respiratory origin. The influence of this pollution was manifold and was due (1) to the presence of the bacillus of tubercle; (2) to the retention of its virulence by this organism in such atmospheres; (3) to the presence of other pathogenic organisms; and (4) to the physical condition of the persons breathing such air. Their first duty in the prevention of consumption must be to get rid of this "air-sewage" which caused more mortality than water-sewage. This work could only be accomplished by copious "ventilation." The standard of ventilation hitherto fixed for dwelling-rooms was 3000 cubic feet per head per hour, in order to reduce the amount of respiratory CO_2 to two parts per 10,000. A better method of judging the efficiency of ventilation was to take the amount of CO_2 in the air as the standard. Although it was the organic matter accompanying the CO_2 which did the harm, and although in [illegible] were not always in proportion, [illegible] the organic material as a te[illegible] away both, it was a good and more readily applied standard than the mere velocity of the entering or out-going currents of air. In the year 1897 a Home Office Committee, of which Dr. Ransome was a member, proposed that the CO_2 present in humified weaving sheds should be made the standard of ventilation; and this measure was embodied in the Cotton Cloth Factories Act of 1898, with the result that a great improvement had taken place in the conditions of labour in these places. A table showing the results was exhibited. Evidence was also given showing that the health of the operatives in these weaving sheds had greatly improved and that in consequence the sickness rate had diminished. The Act of 1898 only applied to a few thousands of male and female operatives, leaving several millions of others, who now performed their labour under the old conditions of insufficient air-supply. Dr. Ransome urged that the same standard should be applied to all "work places" and anticipated that the health of the people who worked in them would benefit to at least the same extent, and that the prevalence of consumption amongst them would be greatly reduced thereby. A plea was also put in for some regulation of the ventilation of other places of public assembly, such as theatres, concert-rooms, churches, chapels, &c. The question of cost was discussed and it was shown that this objection need not be prohibitive.

Dr. T. GLOVER LYON (London), physician to the City of London Hospital for Diseases of the Chest, Victoria Park, London, communicated a paper on

The Air-supply of London.

Air-supply, he said, related to habits or conditions of life. Bad air caused deterioration of health, leading to increased susceptibility to phthisis, and in extreme cases seemed to act specifically in this direction. The respiratory apparatus of the body was capable of temporary adaptations, but pure air was required, though vitiated air might be tolerated for a short time without injurious effect by some persons. Brain work necessitated better air-supply than manual labour. He defined *pure air* as air that might be breathed by most people all through the year without deterioration in health; *fresh air*, air such as would serve continuously for some time, but not indefinitely; and *vitiated air*, such as could be breathed without injurious effect for short periods only of the day. Pure air was not necessary to prevent or even to cure phthisis, as was shown by the results at the London chest hospitals. When Queen Victoria came to the throne the general supply of air to London was perfectly good, and country air could be enjoyed within an easy journey on foot by all Londoners. The annual country health excursion was unknown. At the beginning of King Edward VII.'s reign pure air was unattainable by the majority of His Majesty's subjects dwelling in his capital. Provision of much larger spaces, within easy reach of all, was imperative, for the zones of houses built next to open country were blocked in by others one after another. For every house built or rebuilt adequate park space in near proximity to it should be provided. He considered the present regulations of air-supply to individual buildings quite inadequate, while there was no supervision of any account of the ventilation of buildings. He suggested that (1) regulations should be drawn up for the adequate provision of open spaces in the building and rebuilding of large cities; (2) in the case of schools and public assembly rooms of all kinds provision should be made to admit a standard quantity of fresh air to each person whom the schools or assembly rooms are intended to accommodate; and (3) ventilation generally should be under the supervision of the medical officer of health.

Dr. ESPINA Y CAPO (Madrid) said that the best spittoons to employ were those composed of hygienic paper to be burnt immediately after expectoration. By warning all people to use the spittoon it was possible in some degree to limit the infection. He also recommended that collecting spittoons, which must be placed everywhere, should be constructed of a material easily destructible by fire, so that they might be replaced from day to day.

Mr. C. H. GARLAND ofthe General Post-office referred to the subject of phthisis among their employés.

Dr. R. ALEXANDER. Dr. J. F. J. SYKES (London), Sir HENRY LITTLEJOHN (Edinburgh) and others also took part in the discussion.

THURSDAY, JULY 25TH.

DIVISION IV., THE INTERNATIONAL ASPECTS OF TUBERCULOSIS.

A general discussion was opened by Dr. ALFRED HILLIER (London), who was followed by delegates from various States, among whom we may mention Dr. MONTIZAMBERT, Director-General of Public Health in Ottawa; Professor F. C. ROBINSON, delegate of the State Board of Health of Maine, U.S.A.; and Dr. VAN RYN, Secretary-General of the Belgian National League against Tuberculosis.

SECTION II.

MEDICAL, INCLUDING CLIMATOLOGY AND SANATORIA.

TUESDAY, JULY 23RD.

The meetings of this section were held in the Royal Medical and Chirurgical Society's Rooms, 20, Hanover-square, W., under the presidency of Sir RICHARD DOUGLAS POWELL, Bart., K.C.V.O., who opened the proceedings with a brief introductory speech.

Dr. C. THEODORE WILLIAMS (London), consulting physician to the Brompton Hospital, then discussed

What Influence has Climate upon the Treatment of Consumption?

He said: "Climate has in all ages been considered to exercise an important influence in the treatment of pulmonary tuberculosis, though opinions have differed as to the kind of climate which is most beneficial. In South America, since early times, arrest of tuberculosis has been produced by prolonged residence in the Andes (Archibald Smith, Guilbert, and Weber) without the aid of sanatorium and other treatment, and these successes must be attributed to climate and to climate alone. Numerous authenticated instances of arrest can also be shown as the results of sea voyages, of warm and of cool marine climates, or of dry, warm climates respectively; in fact, it has been proved that the arrest of tuberculosis has occurred in a variety of climates and under very different conditions. The main object is to determine under what climatic conditions arrest of this disease most frequently takes place and what are the real causes of such improvement. In all climatic treatment care must be taken to bring the patient fully under the influence of the atmosphere and to insure a strictly open-air life, with complete hygienic measures, whether in a sanatorium or elsewhere. The climate which best fulfils these conditions need not necessarily be a warm or a cold one, but should be dry, with abundant sunshine, admitting of much exercise and producing appetite and muscular vigour. Tropical climates are excluded on account of their relaxing influence and their favouring bacillary increase.

The principal climates utilised for the treatment of pulmonary tuberculosis may be grouped as follows: (1) marine; (2) dry warm climates; and (3) mountain climates.

Of marine climates the temperate ones of the British Islands have been shown to be suitable for a large number of cases of chronic pulmonary tuberculosis, specially in its strumous form, even when accompanied by pyrexia, and for our countrymen and women the avoidance of long journeys and the certainty of abundant and good food and of home comforts are a great recommendation. The warm marine climates of Madeira, the Canaries, and the West Indies are beneficial in catarrhal tuberculosis, but not as a rule in phthisis generally. Sea voyages are probably the most successful form of marine climates, and provided (1) that the patient's cabin is well ventilated, so that he is sure of abundant fresh air by night and in stormy weather as well as by day, (2) that the food-supply be good and unfailing, and (3) that the voyage be in temperate and not in tropical seas, a sea voyage is often productive of large gain of weight and colour and leads to arrest of tuberculous disease. Sea voyages are most beneficial in (1) hæmorrhagic phthisis, (2) in strumous or scrofulous phthisis accompanied by affections of the glands or joints, and (3) in cases of chronic tuberculous cavity where the disease is limited and unilateral.

Dry warm climates include that of the Desert (especially the Egyptian) and those of the Mediterranean basin. The Desert climate is remarkable for its dryness, sunshine, and its purity and asepticity, and is especially adapted to open-air treatment. Owing to radiation the extremes of temperature are often great. General improvement in consumptives is perhaps more striking than local, but diminution in the amount of lung secretion and reduction of cough usually take place. The Desert climate appears to act more decidedly in preventing the spread of tuberculous disease than in arresting that already present. It seems to benefit most cases of chronic cavity, especially in elderly persons and patients who are incapable of much exercise. The climate of the Riviera and of the Mediterranean basin, as a whole, is cooler and more stimulating, but liable to greater vicissitudes of weather, though not of temperature, than the Desert climate. It is moister than the latter and, compared to the British climate, it is clearer and brighter with a good deal of wind, but free from fog or mist, with a winter mean temperature from 8° to 10° F. higher, with half the number of rainy days and four or five times the number of sunny ones. It can be recommended in chronic phthisis, especially when complicated with inflammatory attacks, in strumous and laryngeal phthisis, and to patients with rather extensive tuberculisation of the lungs, who from feeble circulation, short-windedness, or advancing age are unable to bear the effects of a high altitude.

Mountain or high altitude climates vary according to latitude, but are all characterised by (1) diathermancy, or the increased facility with which the sun's rays are transmitted through the attenuated air, which causes a difference between sun and shade temperatures of 1° F for every rise of 235 feet (Dennison); (2) by their asepticity, as shown by the preservation of meat for long periods; (3) by their physiological effects on the human body, as shown by the tanning of the skin, increase of both pulse and respiration rate, followed after a certain period of residence by a slowing and a deepening of the latter, and an extension of the thorax, also by an increase in the amount of urea and water excreted by the kidneys; more oxygen is absorbed and more carbonic acid is expired by the lungs. The effect on cases of early tuberculous consolidation is remarkable, local pulmonary emphysema is produced around the tuberculous nodules, and the healthy portions of the lung become hypertrophied, necessitating enlargement of the thorax, which can be proved in several ways. Expansion of the chest takes place unless opposed by extensive lung fibrosis or pleuritic adhesions.

It is suggested that the arrest of the tuberculous disease is greatly owing to the pressure on the tuberculous masses by the increasing bulk of lung tissue, which by emptying vessels prevents caseation and cretification of the tubercle. Accompanying these changes are the disappearance of cough and expectoration, improvement in digestion and assimilation, gain of weight, of colour, and of muscular, respiratory, and circulatory power. The high altitudes have produced the best climatic results of all climates in the treatment of phthisis, but they are most successful in cases of early tuberculous consolidation, where they produce complete arrest in by far the larger proportion of patients, and in hæmorrhagic phthisis, but they are not equally successful in cases of excavation which require a longer sojourn to produce arrest The high altitudes are much more beneficial to the young than to the middle aged of both sexes males over 30 years of age and females under 20 benefit least The special effects above named have been noted in the Alps, the Andes, the Rocky Mountains, and are common to all mountain ranges The period of sojourn for patients in any climate must depend on the conditions of the climate and of the individual to be treated and in many instances a change of climate after a prolonged stay has many advantages Contra indications to the various groups of climates were enumerated All climatic treatment should be carried out under as strict medical supervision as sanatorium treatment "

Professor LANNELONGUE, Dr ACHARD, and Dr GAILLARD communicated a paper on

The Comparative Influence of Climate and Individual Resistance in Experimental Tuberculosis
